

ORKA Calorimetry

Proposed Technologies

Corrado Gatto

INFN Napoli

Schematics of ORKA Calorimeter

- **Barrel technology:** Shashlyk/ADRIANO
- **Barrel:** R_{in} : R_{out} : L 70:145:240 cm³
- **Barrel Weigh:** 25-30 ton
- **Barrel segmentation:** 385 towers 32x25 cm² or 32-64 wedges

- **Endcap technology:** CsI (undoped)
- **Endcap size:** dia:L: 98cm:25cm
- **Endcap Weigh:** 1.13 ton
- **Endcap segmentation:** 24 6x5x25 cm³ + 119 8.5x7-8x25 cm³

Photon Veto or Calorimeter

It depends on the process!

Process	Current	ORKA
$K^+ \rightarrow \pi^+ \nu \bar{\nu}$	7 events	1000 events
$K^+ \rightarrow \pi^+ X^0$	$< 0.73 \times 10^{-10}$ @ 90% CL	$< 2 \times 10^{-12}$
$K^+ \rightarrow \pi^+ \pi^0 \nu \bar{\nu}$	$< 4.3 \times 10^{-5}$	$< 4 \times 10^{-8}$
$K^+ \rightarrow \pi^+ \pi^0 X^0$	$< \sim 4 \times 10^{-5}$	$< 4 \times 10^{-8}$
$K^+ \rightarrow \pi^+ \gamma$	$< 2.3 \times 10^{-9}$	$< 6.4 \times 10^{-12}$
$K^+ \rightarrow \mu^+ \nu_{heavy}$	$< 2 \times 10^{-8} - 1 \times 10^{-7}$	$< 1 \times 10^{-10}$
$K^+ \rightarrow \mu^+ \nu_\mu \nu \bar{\nu}$	$< 6 \times 10^{-6}$	$< 6 \times 10^{-7}$
$K^+ \rightarrow \pi^+ \gamma \gamma$	293 events	200,000 events
$\Gamma(Ke2)/\Gamma(K\mu2)$	$\pm 0.5\%$	$\pm 0.1\%$
$\pi^0 \rightarrow \nu \bar{\nu}$	$< 2.7 \times 10^{-7}$	$< 5 \times 10^{-8}$ to $< 4 \times 10^{-9}$
$\pi^0 \rightarrow \gamma X^0$	$< 5 \times 10^{-4}$	$< 2 \times 10^{-5}$

Photon Veto or Calorimeter

Requirements for ORKA

- π^0 rejection $> 10^6\text{-}10^7 \rightarrow \gamma$ inefficiency $< 10^{-3}\text{-}10^{-4}$ above 20 MeV and for impinging angles $90^\circ\text{-}20^\circ$. *Desirable sensitivity down to few MeV*
- Depth $> 20 X_0$
- Accidental rate: 0.011/MHz (in order to keep the same rate of accidentals as in E949)
- Max decay time for scintillator: 8 nsec (to keep the accidentals down)
- Energy resolution: 10-15% @ 200 MeV (from E949), but needs further studies
- Desirable: γ/n identification

Dedicated discussion tomorrow

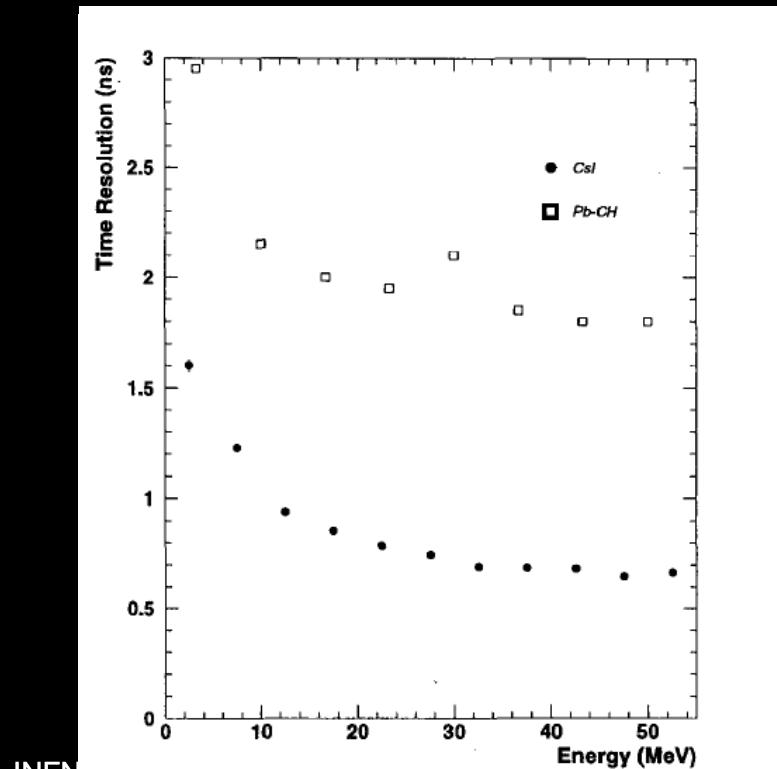

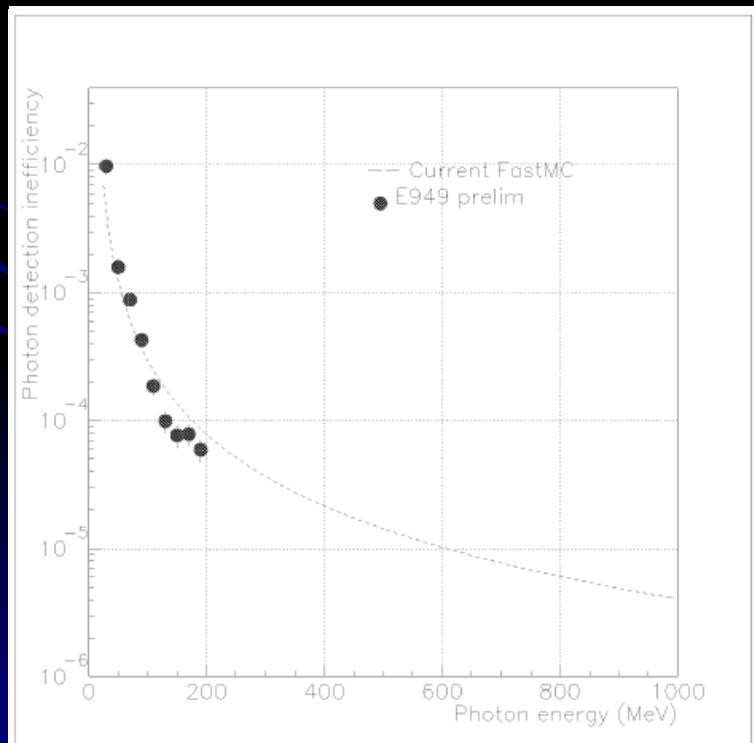

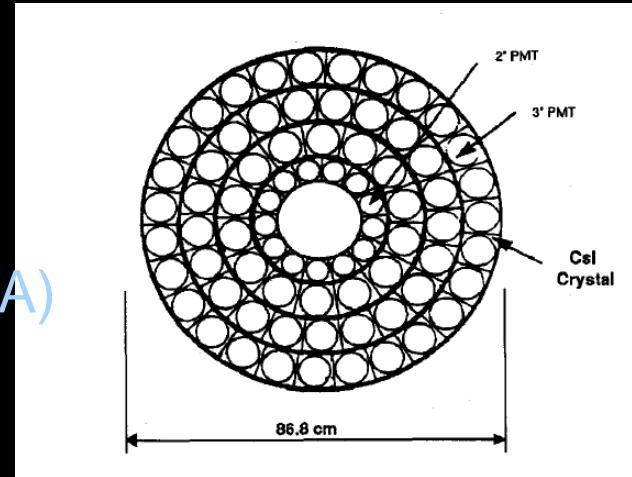

- Light yield $\sim 1\text{pe}/\text{MeV}$
- $X_0 < 3\text{cm}$; $\langle \rho \rangle > 3 \text{ gr/cm}^3$
- Threshold: compromise between low inefficiency & low accidentals
- Inorganic scintillators and/or Cerenkov radiator
- Dual-readout calorimetry

See A. Mazzacane's talk

ORKA Endcap Calorimeter

- Re-use E949 endcap calorimeter
- 25 cm CsI (undoped) crystals
- 13.5 X₀ total depth (may be not enough at ORKA)
- 10 nsec decay constant (+ slower component)
- $\Delta E/E = 10.6\%$ for π^0 from $K_{\pi 2}$ decays (245.6 MeV)

Technologies For Barrel

Shashlyk

- **Pro**
 - Cheap
 - Well established technology
 - Extensive test beam
- **Cons**
 - Sampling fluctuations
 - Inadequate for $E_\gamma < 50$ MeV
 - Large inefficiency for low energy photon

ADRIANO with heavy glass or PbF₂

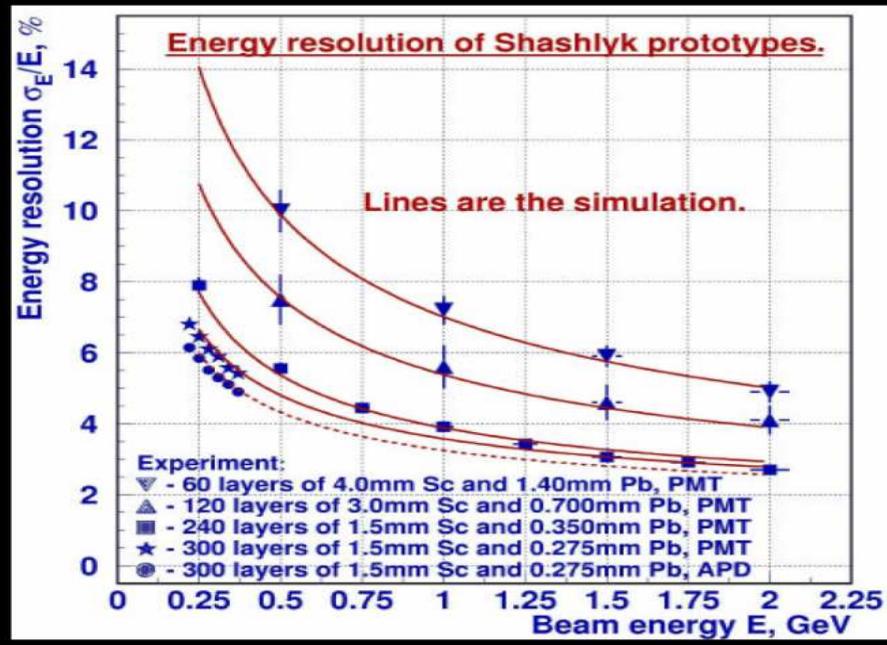

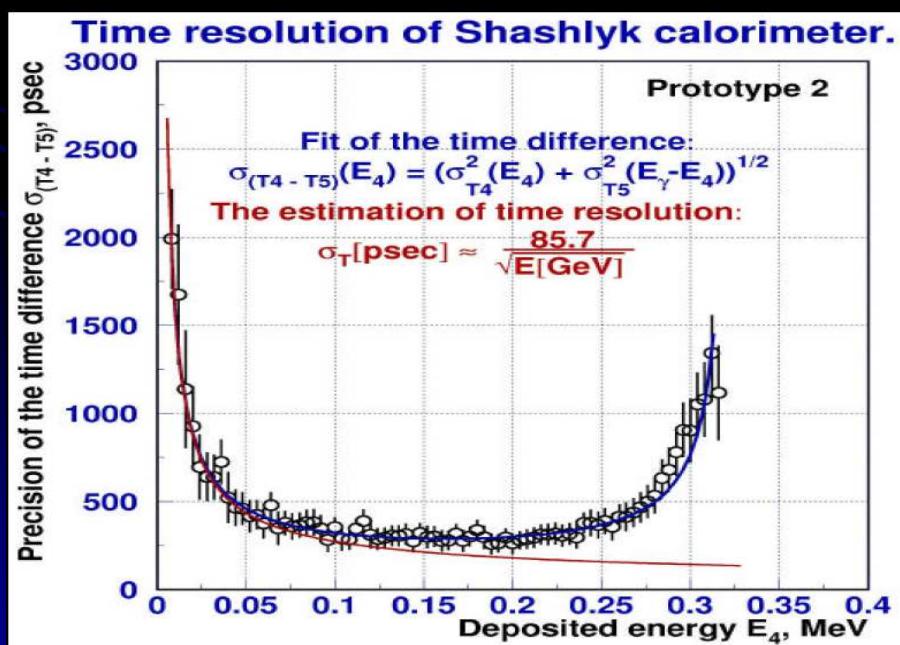

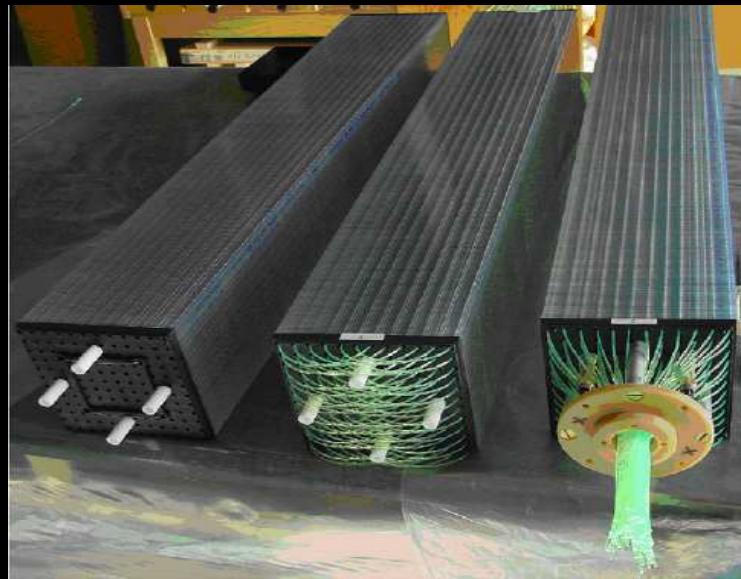

- **Pro**
 - Integrally active calorimeter
 - Higher detection efficiency
 - S vs C provides PID
- **Cons**
 - More expensive
 - Novel technology
 - Tested only at high energy (500 MeV)

ADRIANO in single readout mode

- **Pro**
 - Integrally active calorimeter
 - Highest detection efficiency
- **Cons**
 - Also expensive
 - Untested technology
 - No PID

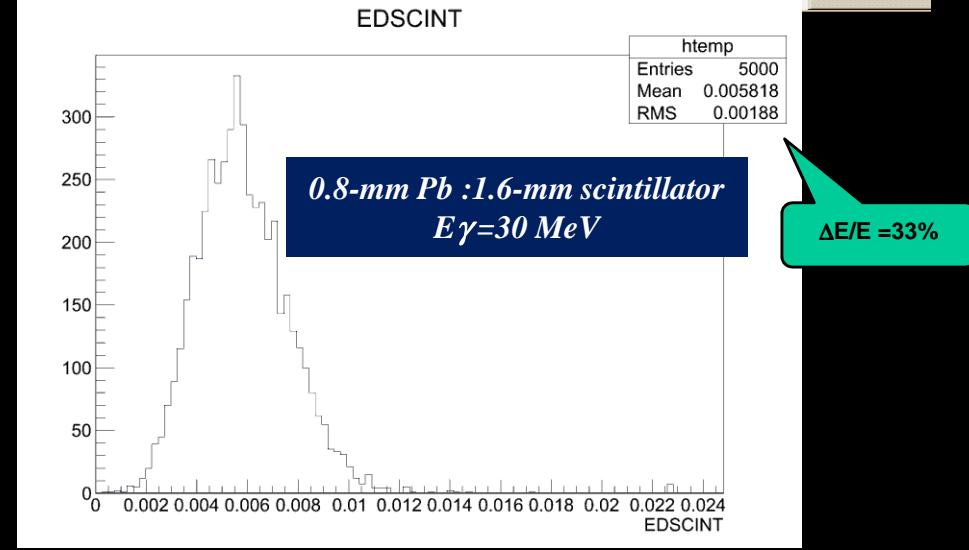

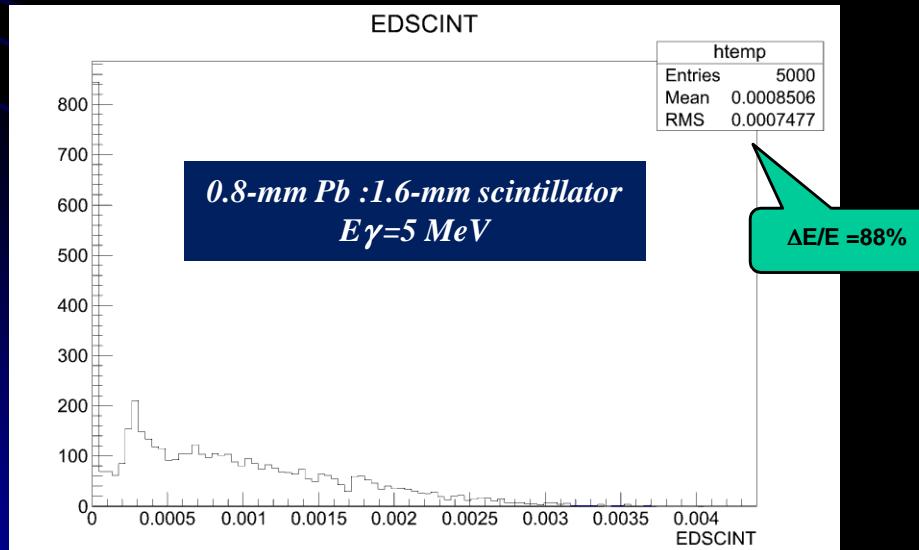

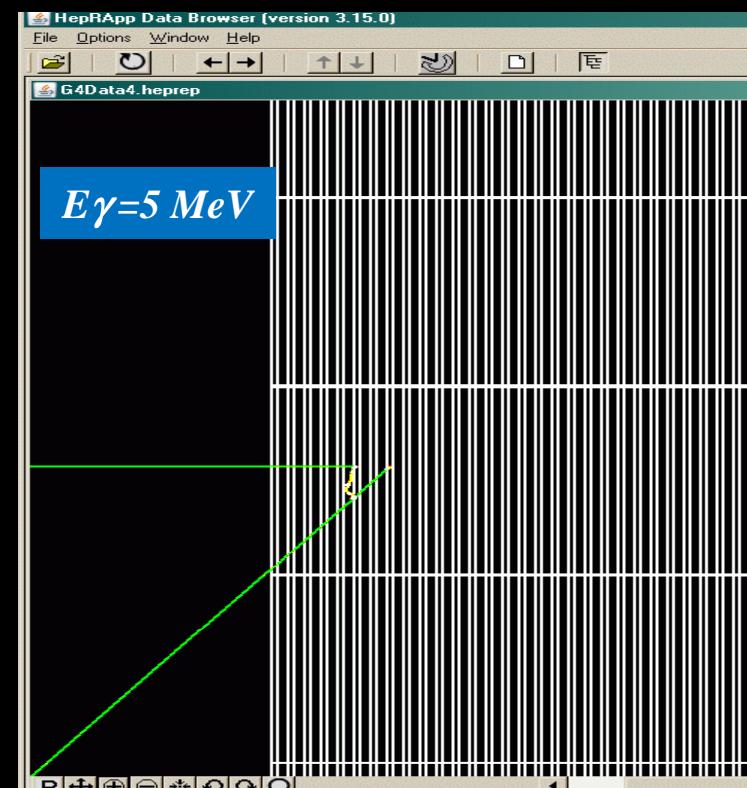

Shashlyk Barrel Calorimeter

- 155 interleaved layers of 0.8-mm lead and 1.6-mm scintillator readout by 400 WLS
- Sampling fraction: 33%
- $X_0 = 1.2 \text{ cm}$; $\langle \rho \rangle \approx 4 \text{ gr/cm}^3$
- L.Y.: 0.75-1.2 pe/MeV
- Energy resolution: $2.9\text{-}4.1\%/\sqrt{E}$
- Time resolution: $90\text{-}100 \text{ psec}/\sqrt{E}$

Shashlyk Potential Problems

- Range of Compton e^- in Pb from low energy γ is about 0.5 mm
- Effective absorber thickness changes as $\text{tg}^{-1}\theta$ (~ 2.75 at $\theta=20^\circ$)
- WLS fibers have 1/10 light yield than scifi: potential crack from channeling in 0.9% volume (holes are 1.3 mm)
- Beam test of 300 layers of 0.275mm Pb/1.5mm scintillator
 - E_{beam} : 50-1000 MeV
 - 85% sampling fraction (rather than 33%)
 - $X_0 \sim 3.5\text{cm}$; $\langle p \rangle \approx 2.75 \text{ gr/cm}^3$
 - Use Y11 (too slow for ORKA): expect a 30% lower l.y.
- Large sensitivity to neutrons with no PID
- Energy resolution is very poor for $E\gamma < 20 \text{ MeV}$

See A. Mazzacane's talk

ADRIANO: A Dual-Readout Integrally Active Non-segmented Option

- Fully modular structure
- 2-D with longitudinal shower CoG via light division techniques

- **Cells dimensions:** 4x4x180 cm³
- **Absorber and Cerenkov radiator:** lead glass or bismuth glass ($\rho > 5.5 \text{ gr/cm}^3$)
- **Cerenkov light collection:** 10/20 WLS fiber/cell
- **Scintillation region:** scintillating fibers, dia. 1mm, pitch 4mm (total 100/cell) optically separated from absorber
- **Particle ID:** 4 WLS fiber/cell (black painted except for foremost 20 cm)
- **Readout:** front and back SiPM (Scifi only)
- **CoG z-measurement:** light division applied to SCSF81J fibers (same as CMS HF)
- **Small tg($\theta_{S/Q}$):** due to WLS running longitudinally to cell axis ($\theta_{\text{Cerenkov}} < \theta_{\text{Snell}}$ for slower hadrons).

ADRIANO Light Yield and Hadr. Resolution

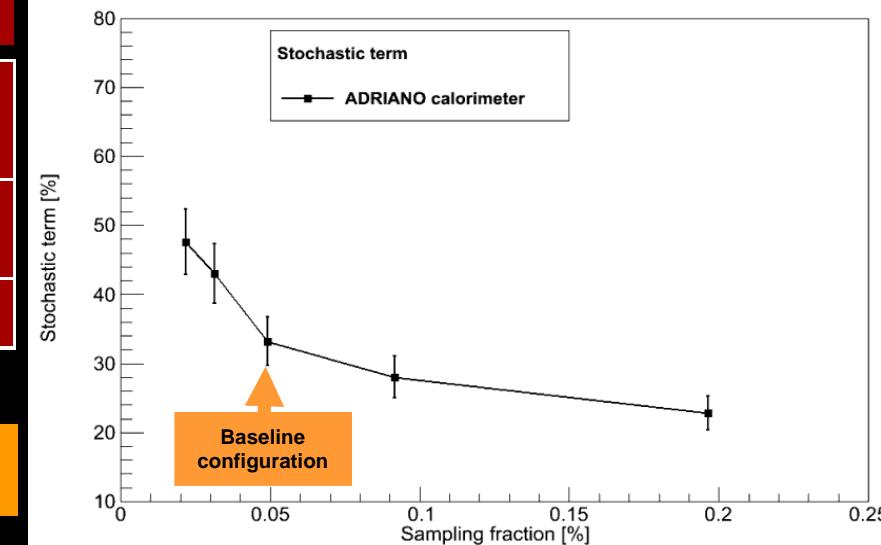

Integrally Active with Double side readout (ADRIANO)

	Sampling								
Pitch [mm ²]	2x2	3x3	4x4	5x5	6x6	4x4	4x4	4x4 capillary	Sampling
Diameter	1mm	1mm	1mm	1mm	1mm	1.4mm	2mm		
$\langle p_{\text{es}}/\text{GeV} \rangle$	1053	430	254	163	124	500	110	250	200
$\langle p_{\text{ec}}/\text{GeV} \rangle$	340	360	360	355	355	355	350	350	7.5

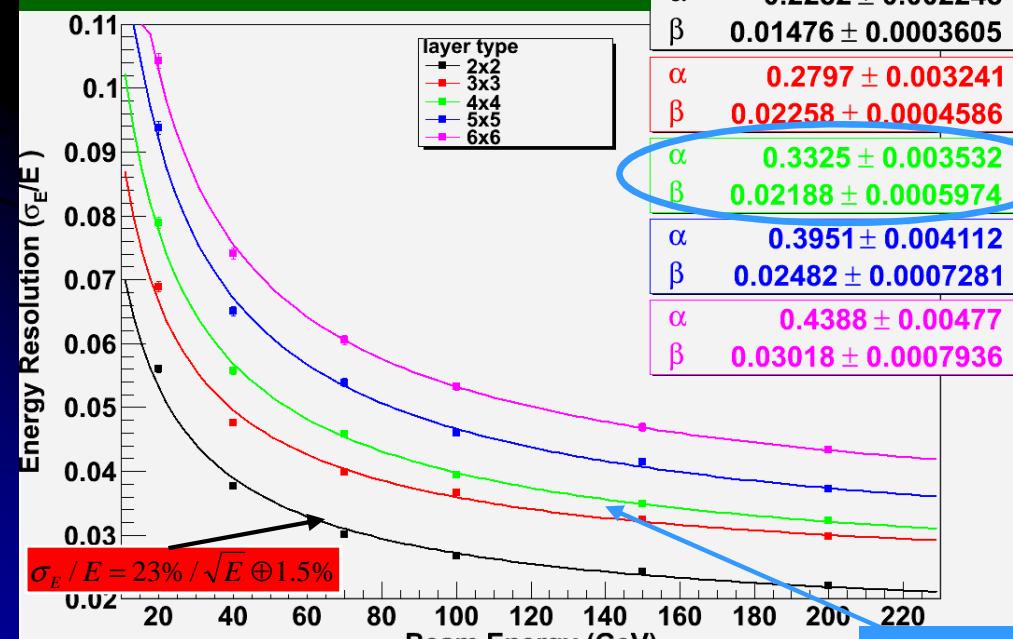

Baseline configuration

1-side readout

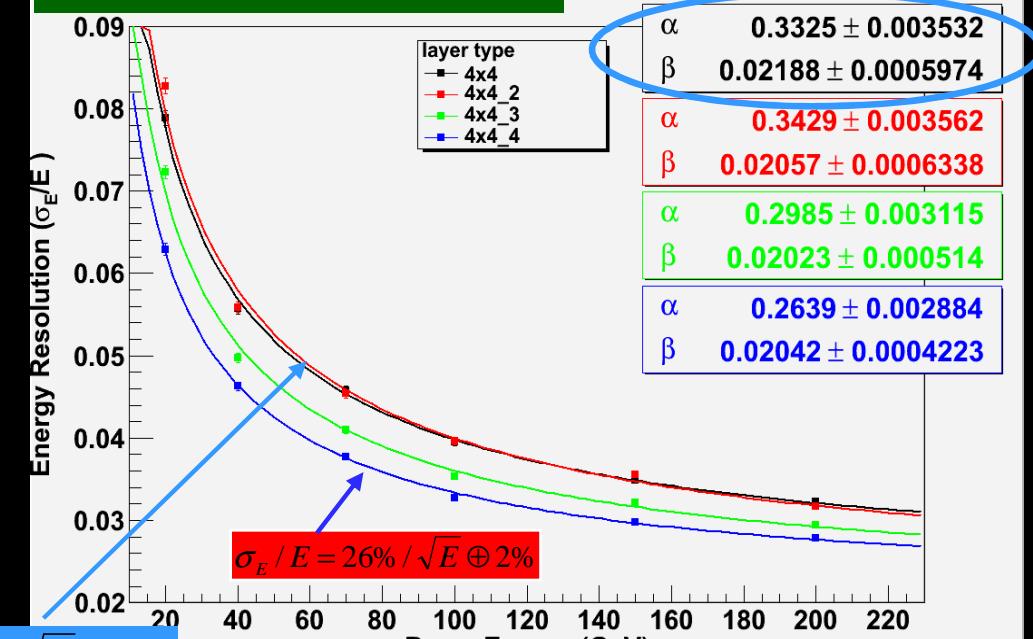

Resolution vs Scifi sampling fraction - ADRIANO Calorimeter

Fiber pitches: 2mmx2mm through 6mmx6mm

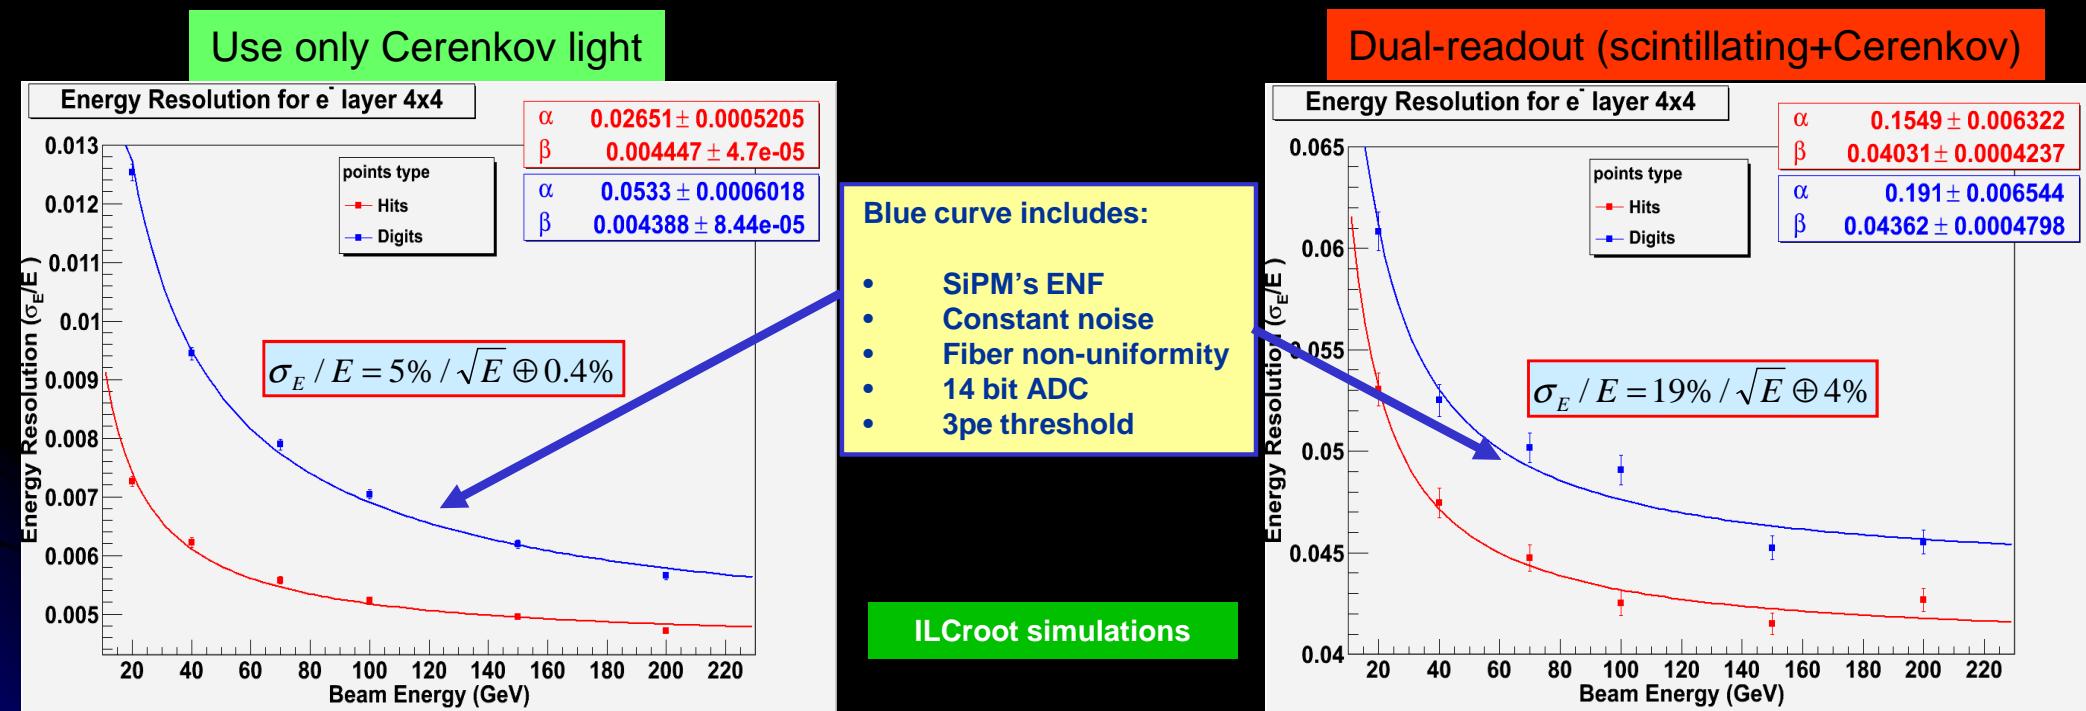

fiber diameter: 1mm – 1.4mm – 2 mm

ADRIANO EM Resolution (with and without instrumental effects)

- Compare standard Dual-readout method vs Cerenkov signal only (after electron-ID)
- Blue curve includes instrumental effects. Red curve is for perfect readout

- Using Cerenkov signal only for EM showers gives $5\%/\sqrt{E}$ energy resolution while full fledged dual-readout gives only $19\%/\sqrt{E}$ (including FEE effects)

ADRIANO does not need a front EM section
If Cerenkov light yield is large enough

Preliminary 11 Prototypes Performance at Test Beam

Prototype	Glass	gr/cm ³	L. Y./GeV	Notes
5 slices, machine grooved, unpolished, white	Schott SF57HHT	5.6	82	SiPM readout
5 slices, machine grooved, unpolished, white, v2	Schott SF57HHT	5.6	84	SiPM readout
5 slices, precision molded, unpolished, coated	Schott SF57HHT	5.6	55	15 cm long
2 slices, ungrooved, unpolished, white	Ohara BBH1 (BiO ₂)	6.6	65	
5 slices, scifi silver coated, grooved, clear, unpolished	Schott SF57HHT	5.6	64	15 cm long
5 slices, scifi white coated, grooved, clear, unpolished	Schott SF57HHT	5.6	120	
10 slices, white, ungrooved, polished	Ohara PBH56	5.4	30	DAQ problems
10 slices, white, ungrooved, polished	Schott SF57HHT	5.6	76	
5 slices, wifi Al sputter, grooved, clear, polished	Schott SF57HHT	5.6	30	2 wls/groove
5 slices, white, ungrooved, polished	Schott SF57HHT	5.6	158	Small wls groove
2 slices, plain, white	Ohara BiO ₂ experimental	7.5	-	DAQ problem

- Analysis still ongoing
- Calibration problematic for DAQ issues and degrading of PMTs from He leaks
- Need further confirmation of the results

ADRIANO for ORKA: baseline layout

- **150 layers; 2mm PBH56/SF57 + 2mm fast scintillator (BC408 or SN88)**
 - $X_0 = 2.9 \text{ cm}$; $\langle \rho \rangle = 3.5 \text{ gr/cm}^3$; Depth = $21 X_0$
- **Detector layout: 2.5m longitudinal layers with 2-sides readout in 64 azimuthal sectors (E949/KLOE approach)**
 - $5.6^\circ/\text{sector}$; 9.5-13.5 cm sector width
 - Towers with back readout also considered, but potentially inefficient
- **Scintillator readout; 1mm BCF92 in grooves 1.6 cm apart**
 - $\lambda(\text{BCF92}) = 350 \text{ cm}$; 1000 fibers/sector bundle lead in 10 units
- **Glass readout; 1mm BCF92 in grooves 1.6 cm apart**
 - $\lambda(\text{BCF92}) = 350 \text{ cm}$; 1000 fibers/sector bundle lead in 10 units
- **Total density of fibers: $3.1/\text{cm}^2$**
 - Compare to original ADRIANO: 6.2 fibers.cm^2

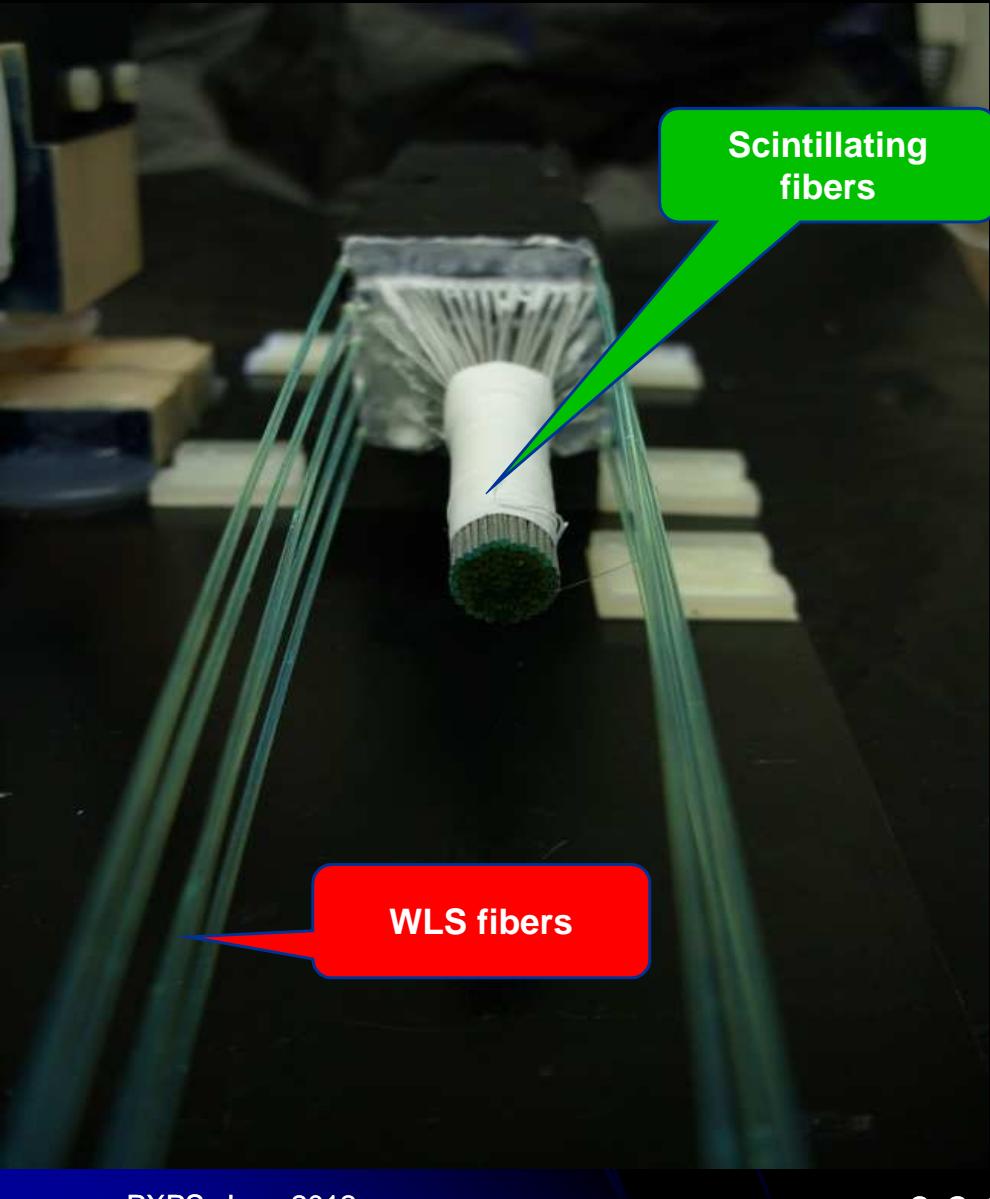

Needs
Optimization
For ORKA

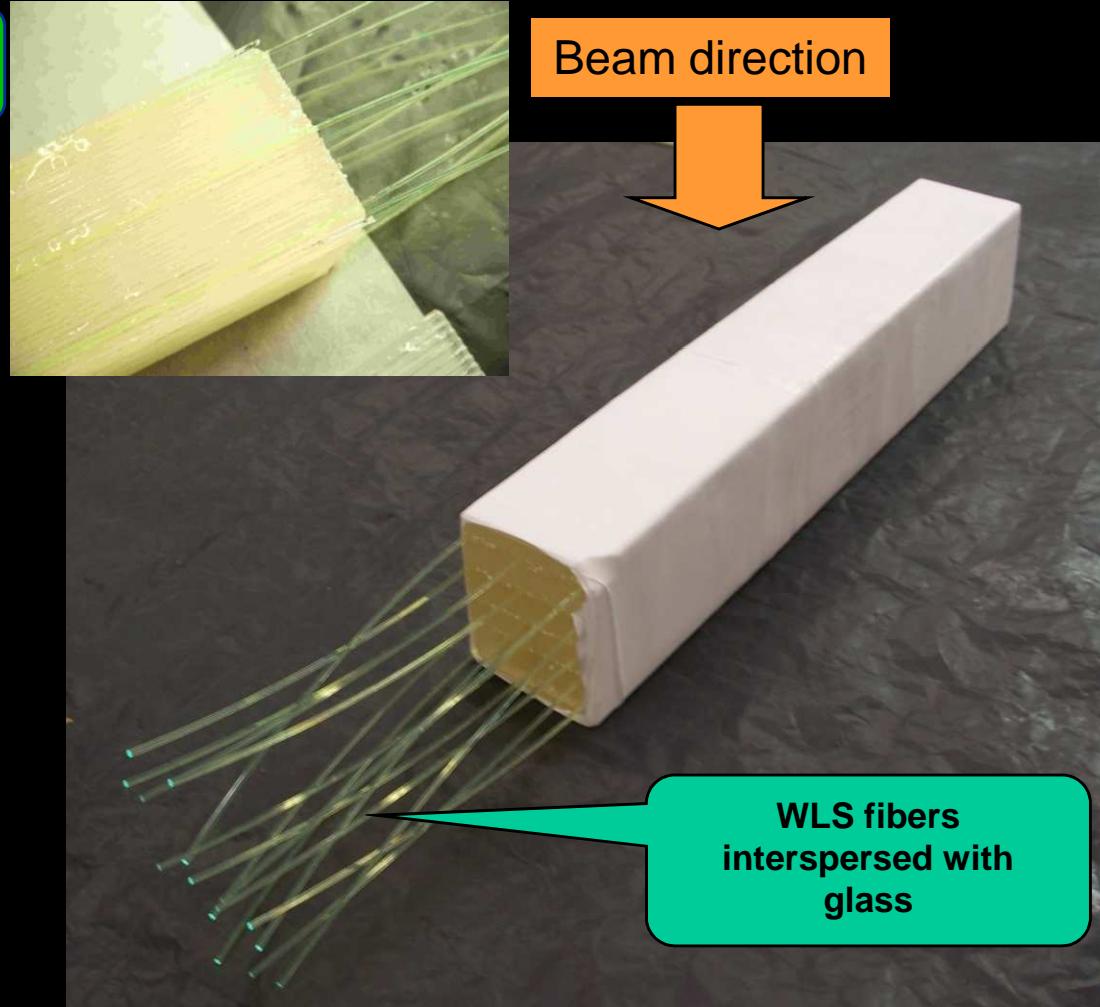

Lots of Cerenkov photons when n_D is about 1.9 or greater

ADRIANO Applications

*Dual-readout Calorimetry
(compensate e/h fluctuations)*

*Imaging Calorimetry
(spatially resolve the shower in 3D)*

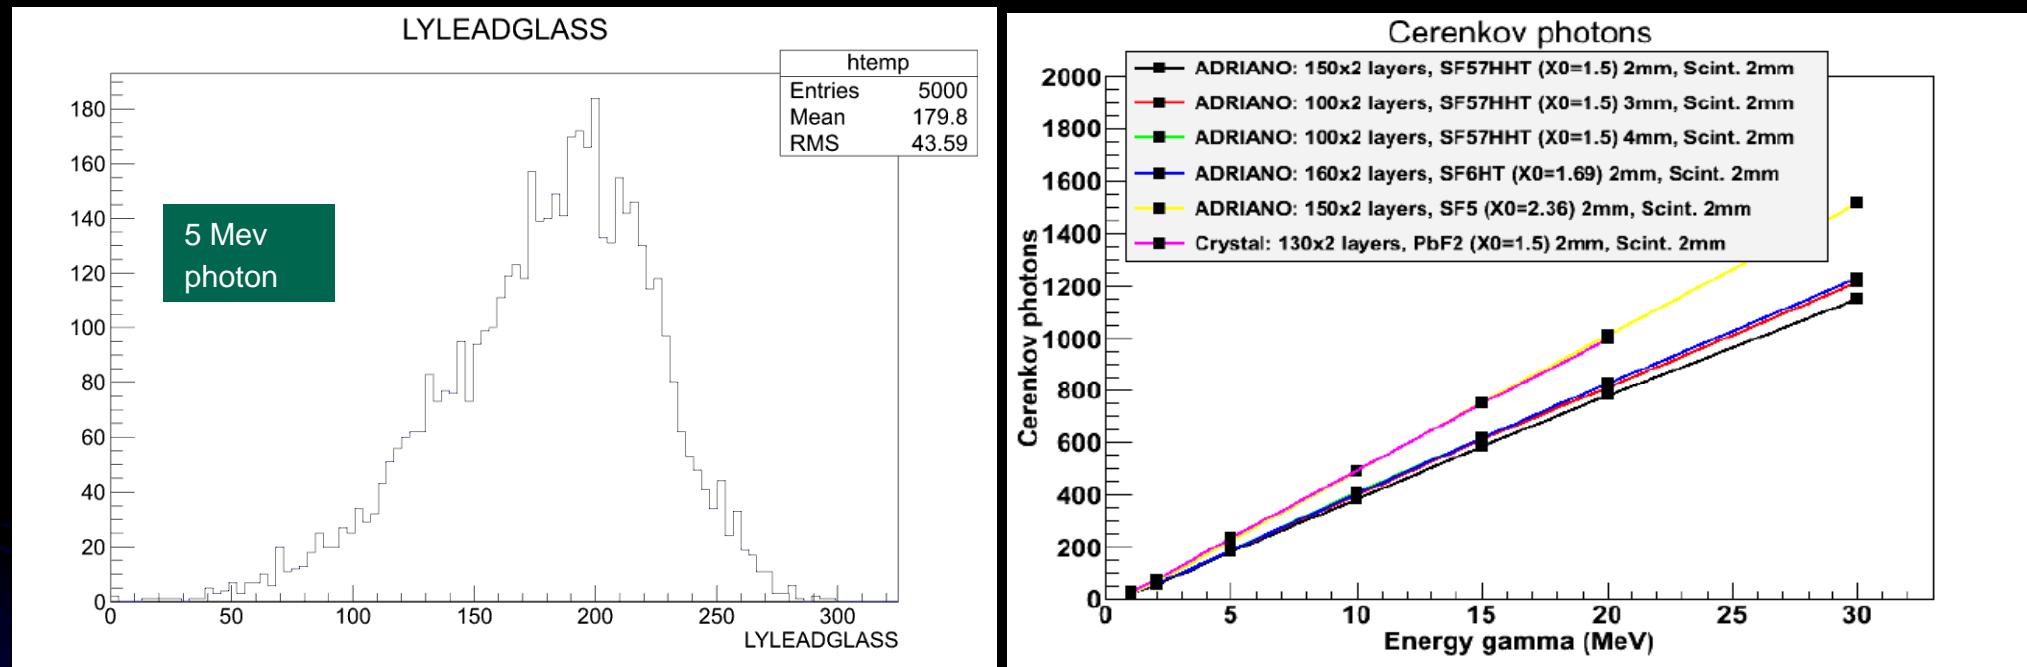

Glass vs Crystals

	Glass	Crystals
Light production mechanism	Only Cerenkov (minor fluorescence with some SF glasses)	Cerenkov + scintillation
Stability vs ambiental (temperature, humidity, etc)	Excellent	Poor
Stability vs purity	Very good if optical transmittance is OK	Very poor
Longitudinal size	Up to 2m	20-30 cm max
Cost	0.8 EUR/cm ³	10-100 EUR/ cm ³
Time response	prompt	Slow to very slow (with exceptions)
n_d	1.85-2.0 (commercially available) 2.25 (experimental)	1.85-2.3
Density	6.6 gr/cm ³ (commercially available) 7.5 gr/cm ³ (experimental)	Up to 8-9 gr/cm ³
Radiation hardness	Medium (recoverable via UV annealing for Pb-glass) or unknown (for Bi-glass)	varies

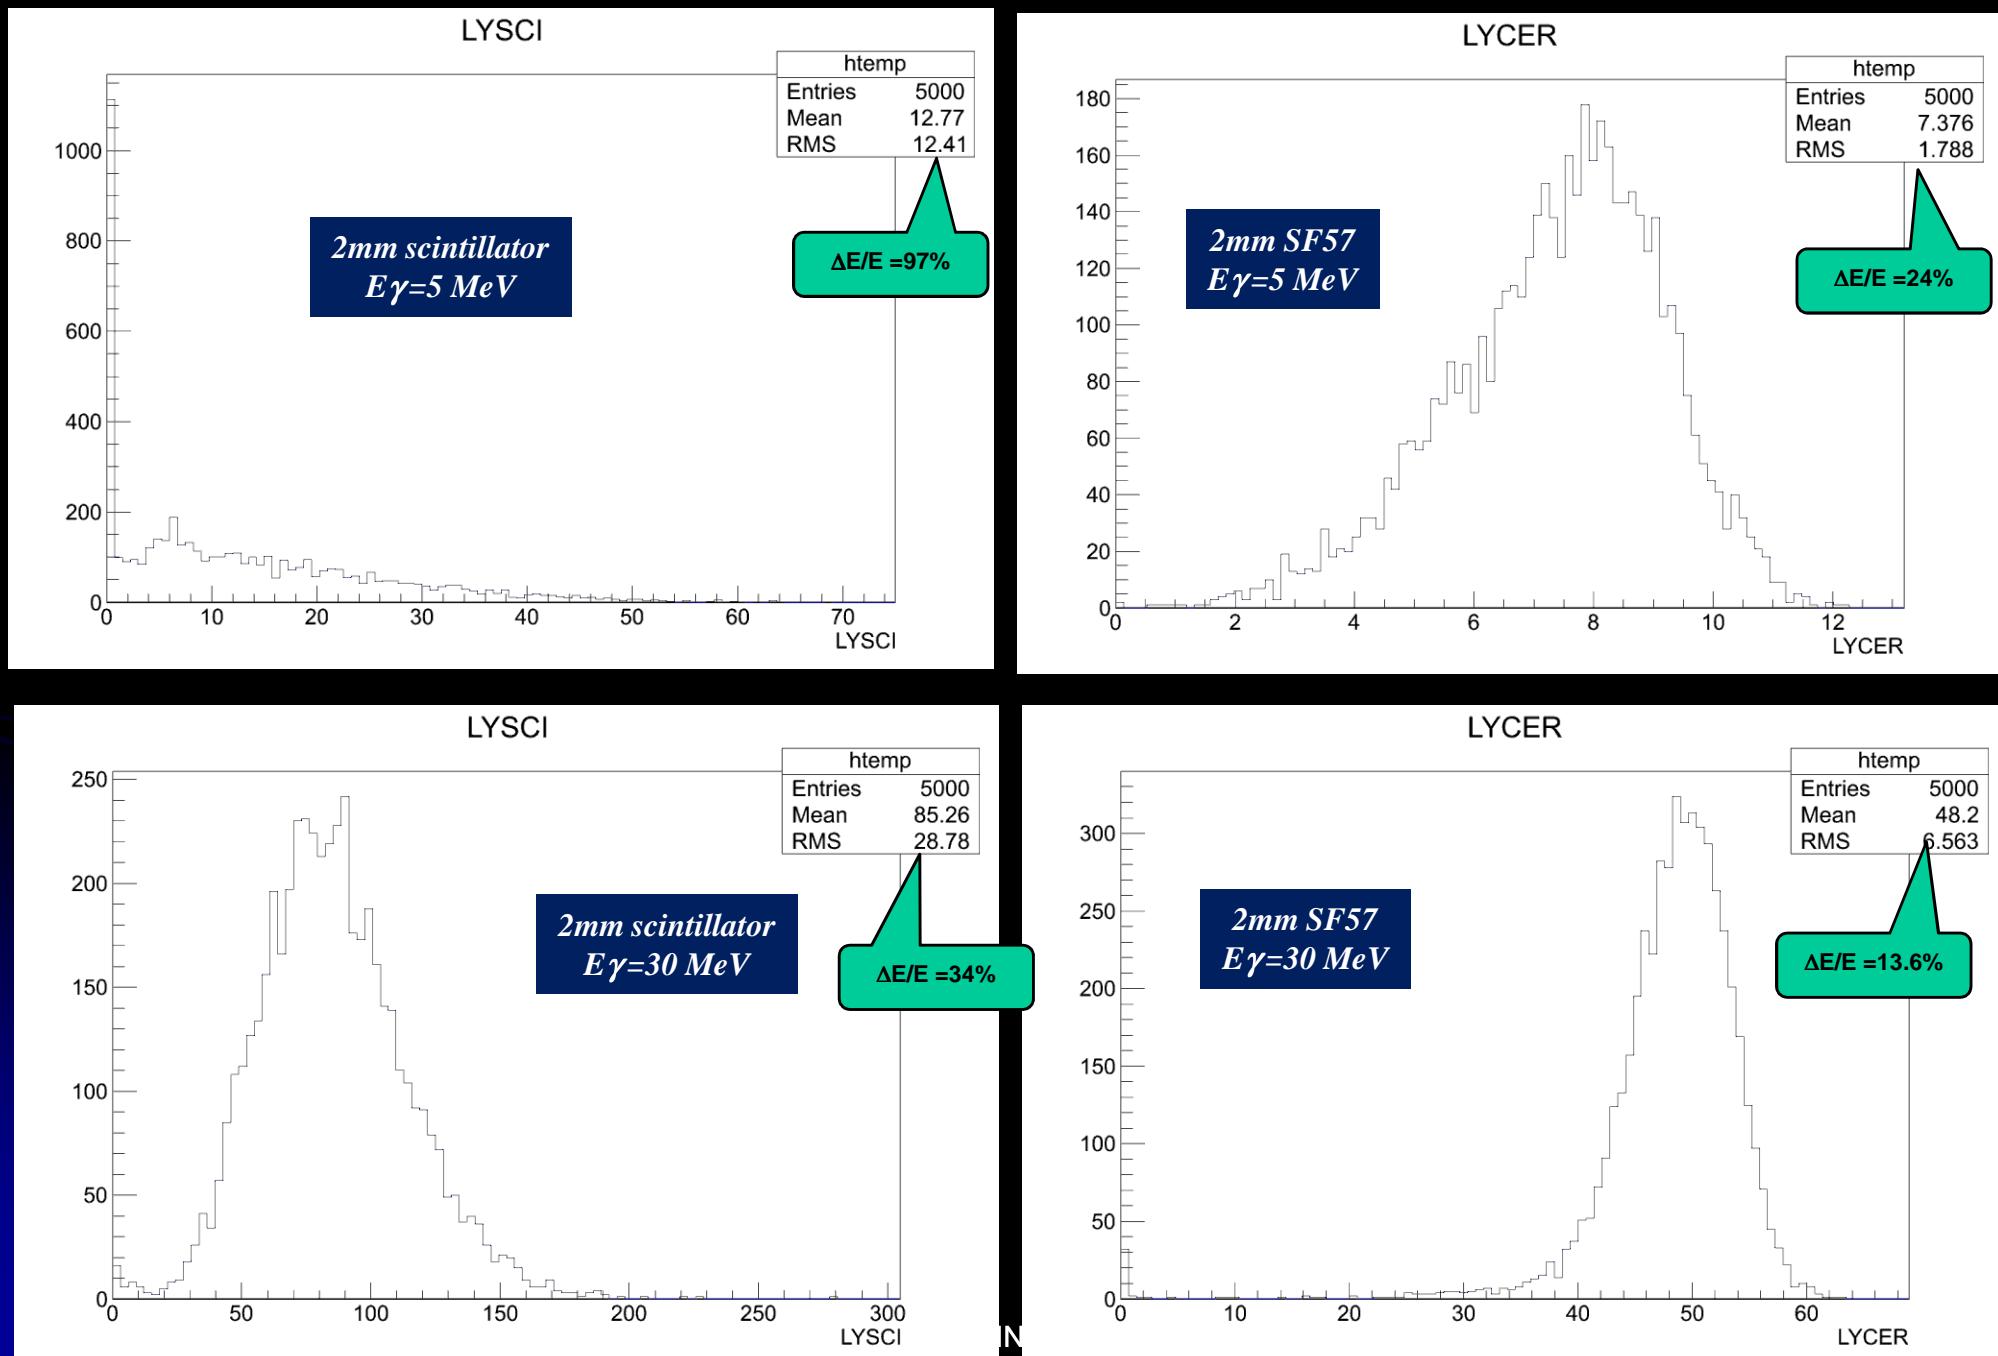

Expected Cerenkov Light at Low Energy

- Cerenkov photons reaching the surface of 2mm optical glass are very abundant

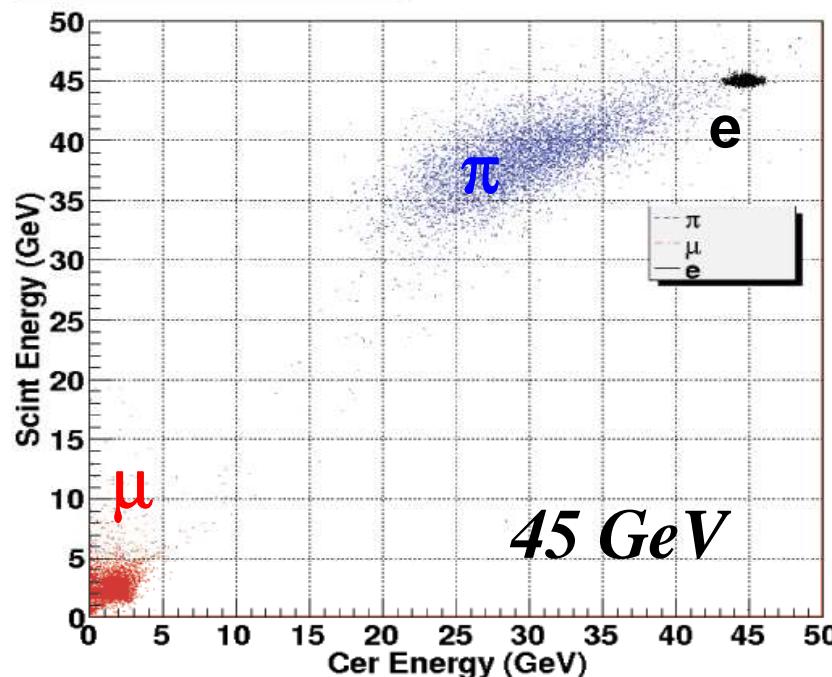

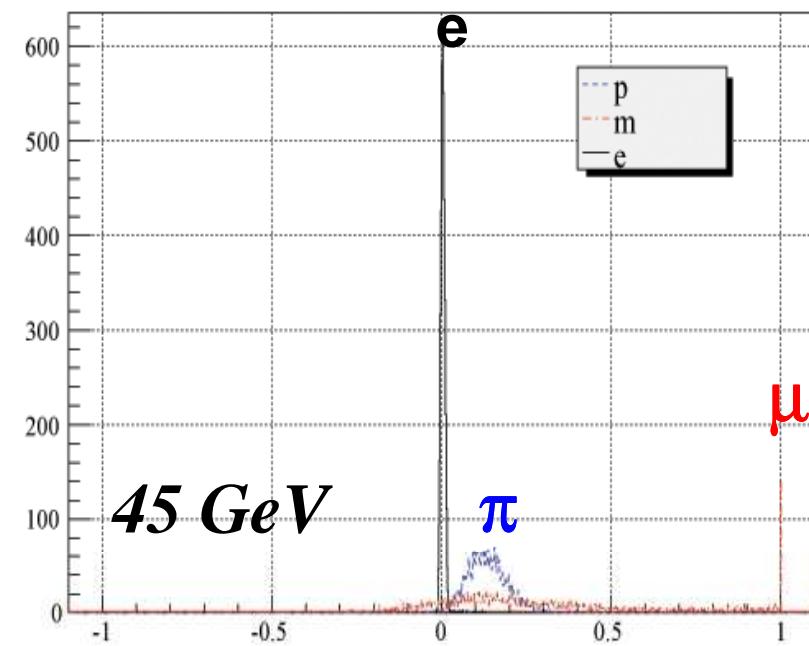

- Use two techniques to capture them
 - WLS fibers in longitudinal grooves (original ADRIANO approach for hadronic detectors)
 - WLS plates facing the glass (novel techniques under development for ORKA)

Simulated Light yield from Scintillator and Glass

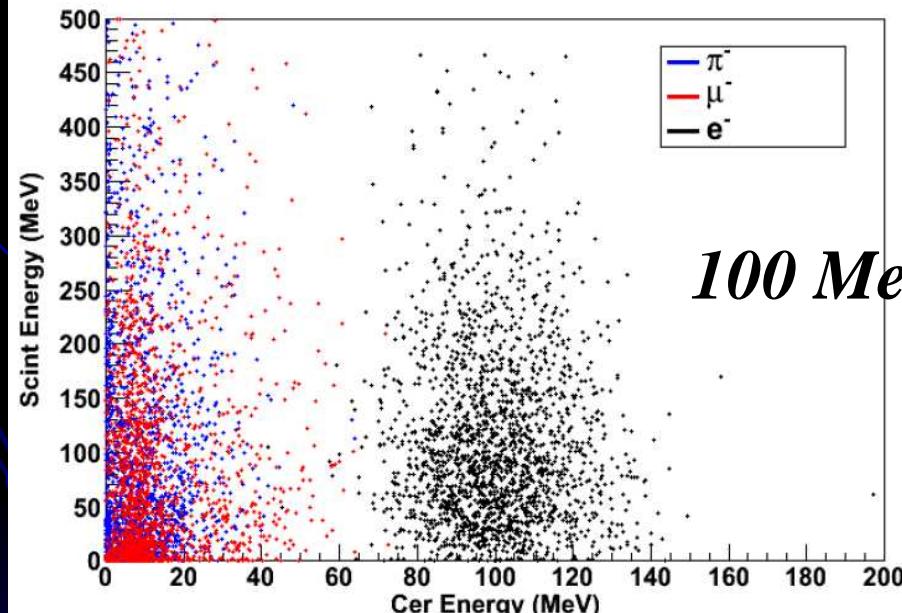

Particle Identification in Dual Readout Calorimeters

Cer Energy vs Scint Energy

 $(S-C)/(S+C)$ 

Cer Energy vs Scint Energy

ADRIANO in Single-readout Mode

- Same layout as in dual-readout case, but put glass slices and scintillating plates in optical contact
- Dope the scintillator in a custom way so it is able to capture the Cerenkov light and WLS it (A. Pla)
- Transport the (two) WLShifted lights to the photo-sensor

• Advantages:

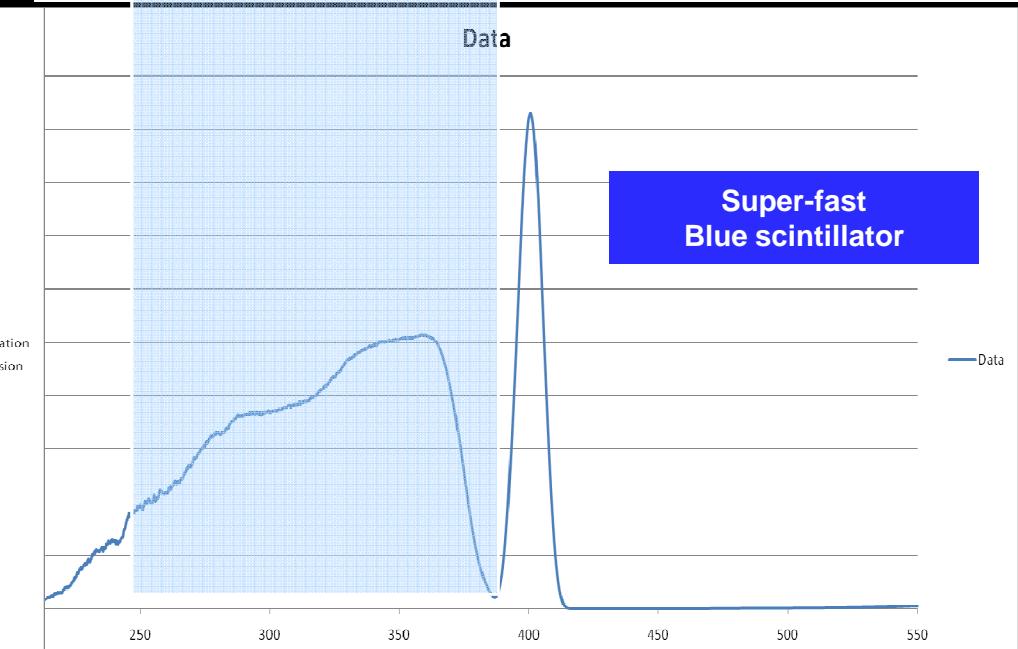

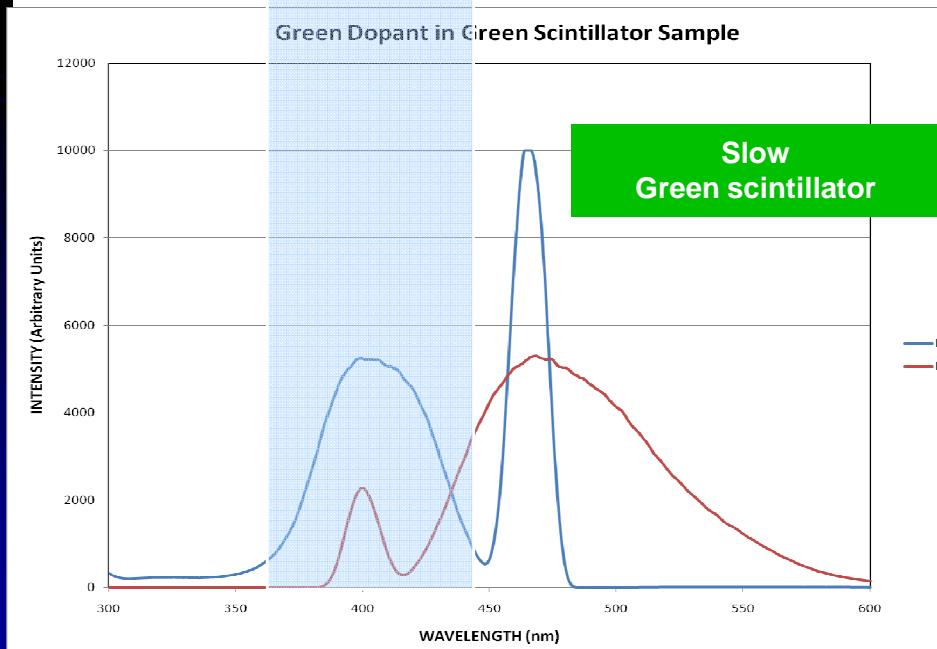

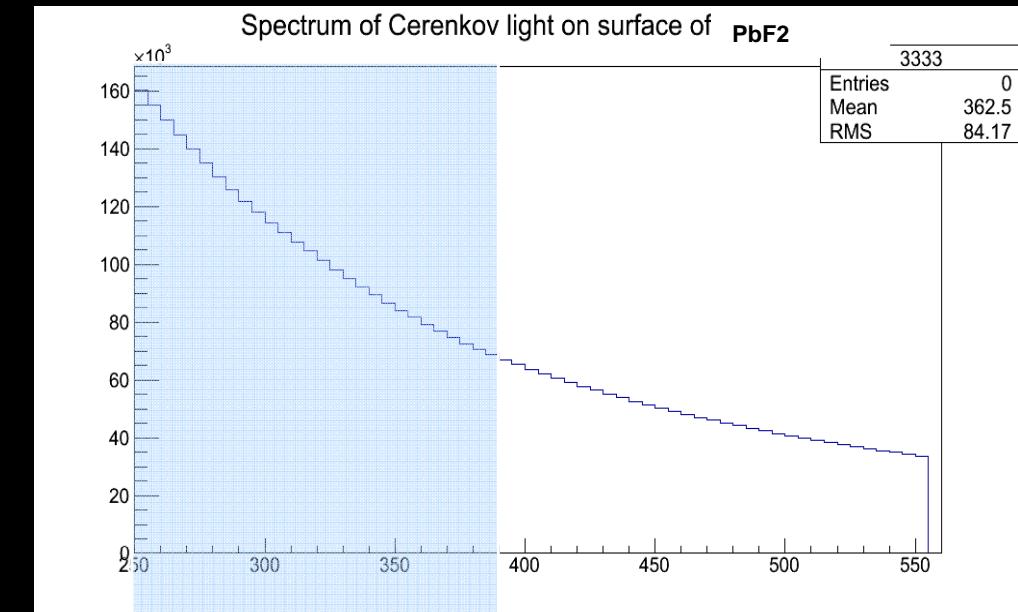

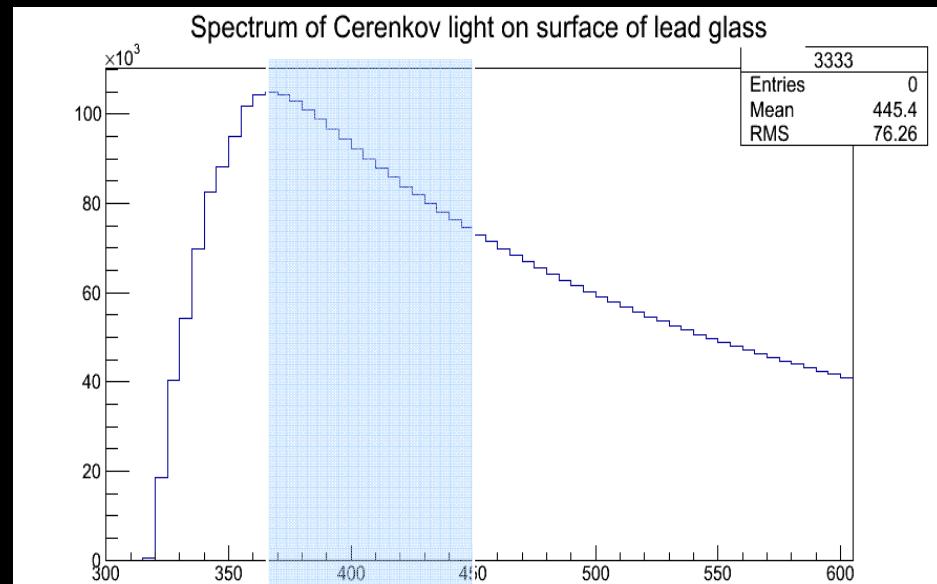

- Totally transparent detector, with no optical boundaries
- If Cerenkov light is not captured by nearest WLS, there are 149 more chances to be captured by another

Make efficient use of plastic plates as scintillators and WLS for Cerenkov light

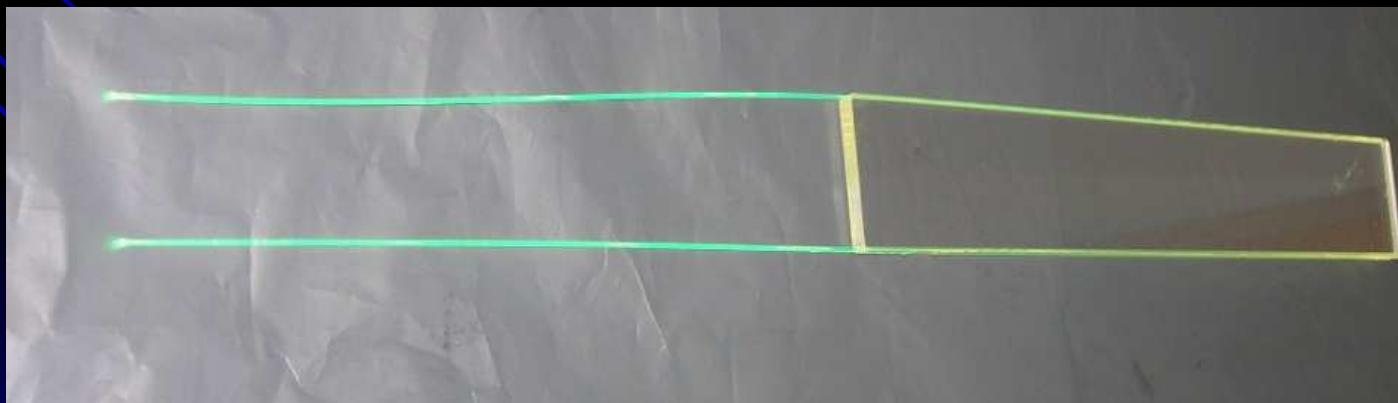

- Two light transport techniques under consideration

Glass vs PbF₂

Main Issues

- PbF₂ version will use WLS fibers for light capture from scintillator
- Glass version use no fibers (a' la E949)
- Need to optimize:
 - Light transmission from glass to polystyrene
 - Already under development for ADRIANO at High Energies
 - Scintillating dye to better match Cerenkov spectrum
- LAPD will be a perfect complement when matched to the external surface of the barrel
- Novel technique: require extensive R&D
- **Caveat: green scintillators are slow (9 nsec or slower)**

Overcoming the Limitations of a 2-D Calorimeter

- ***ADRIANO* for ORKA is a 2-D calorimeter**

- Easier to build and to calibrate
- Fewer number of channels
- No cracks nor unhomogeneities due to longitudinal segmentation

However, in principle, it misses the ability to determine the longitudinal shower profile

- ***Two possible solutions to measure z-coordinate***

- Time difference measurement
- Light division measurement

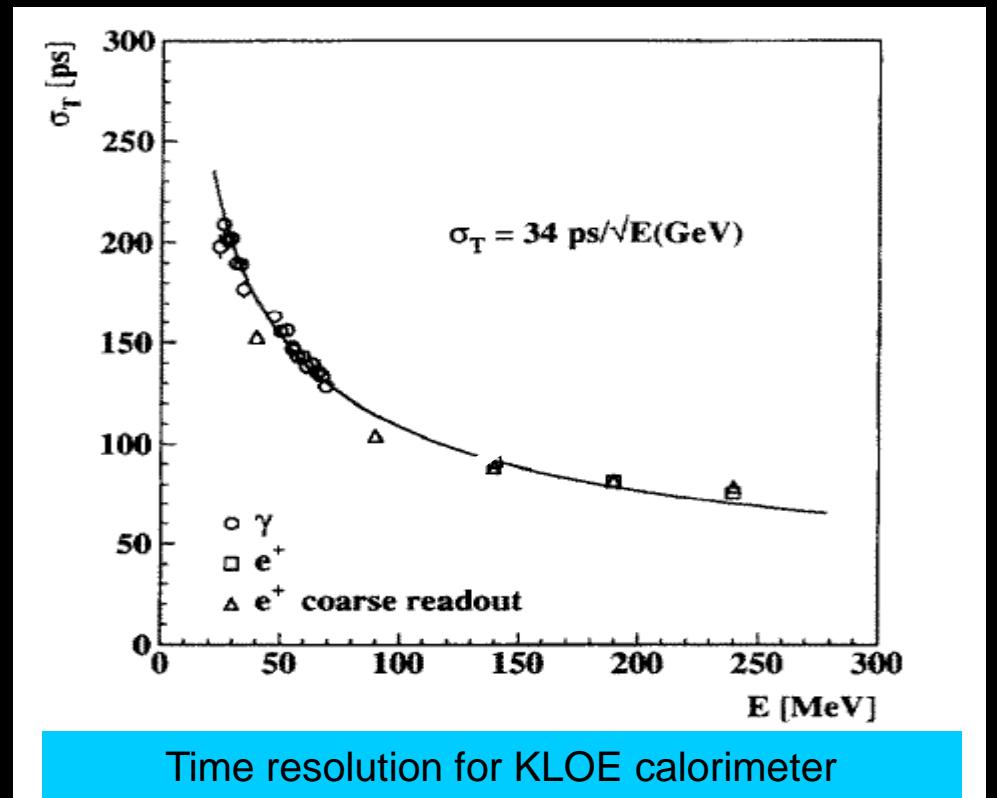

Adding the 3rd Dimension with time difference methods

- Already implemented for KLOE spacial (4.3m long, 0.5mm Pb, 15% sampling)
- Requires 25psec time measurement on both sides (TDC/WFD)
- Assume (pessimistically) the same resolution as KLOE and $v_{\text{fiber}}=17.2 \text{ cm/nsec}$ (for polystyrene with $n_D=1.58$)

$$\sigma_z = \frac{6 \text{ mm}}{\sqrt{E}}$$

- Or: $\sigma_z = 19 \text{ mm at } 100 \text{ MeV}$
- Requires z-dependent time measurement corrections:

$$\sigma_T(z) = \sigma_T(0) \sqrt{\cosh(z/\lambda)}$$

Adding the 3rd Dimension with light division methods

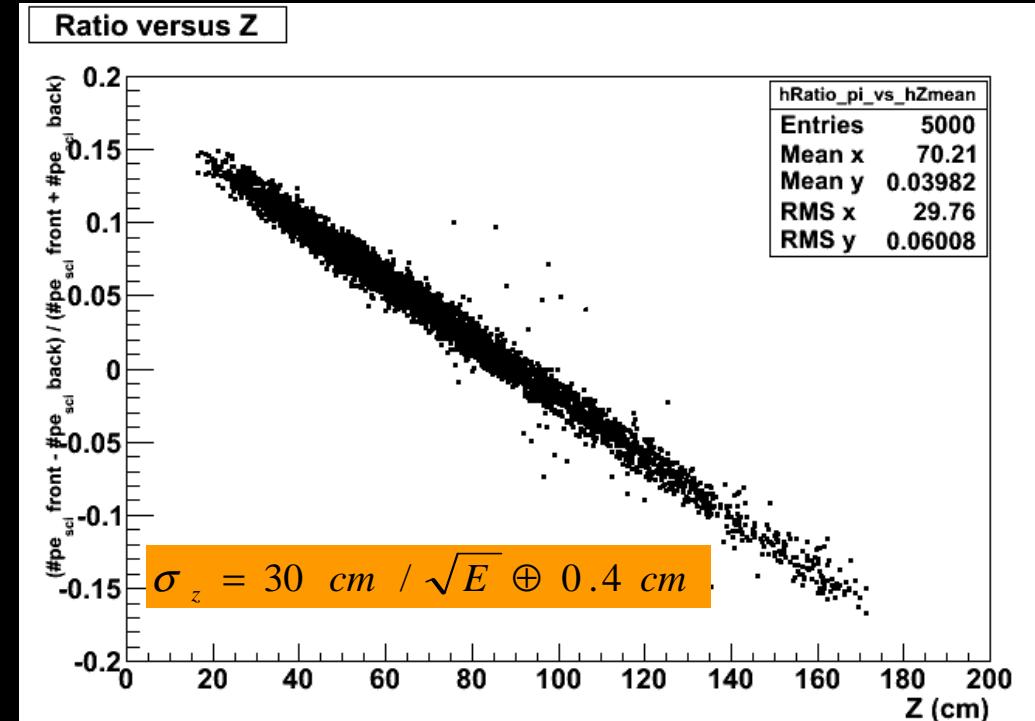

- Determine Center of Gravity of showers by ratio of front vs back scintillation light
- It works because $\lambda_{81J} = 3.5m$
- Similar to charge division methods in drift chambers with resistive wires
- A technique already adopted by UA1 and ZEUS

100 GeV pions

Instrumental effects included in ILCroot :

- SiPM with ENF=1.016
- Fiber non-uniformity response = 0.6% (scaled from CHORUS)
- Threshold = 3 pe (SiPM dark current < 50 kHz)
- ADC with 14 bits
- Constant 1 pe noise.

Front vs back Scintillation light vs true shower CoG

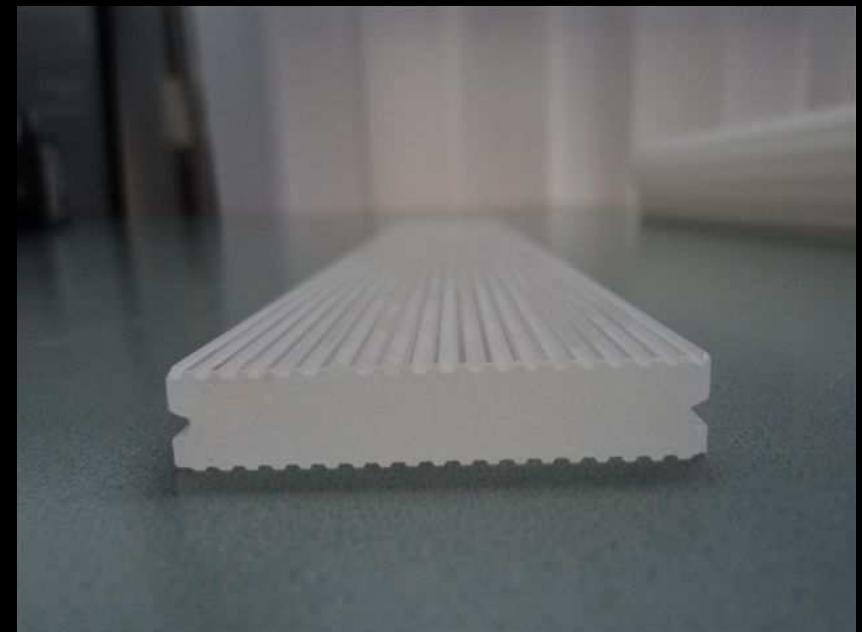

Fabrication Technology #1: Diamond tools machining

- Pro

- Minimal R&D required
- Room temp (min effect on n_D)
- It allows construction of longer cells

- Cons

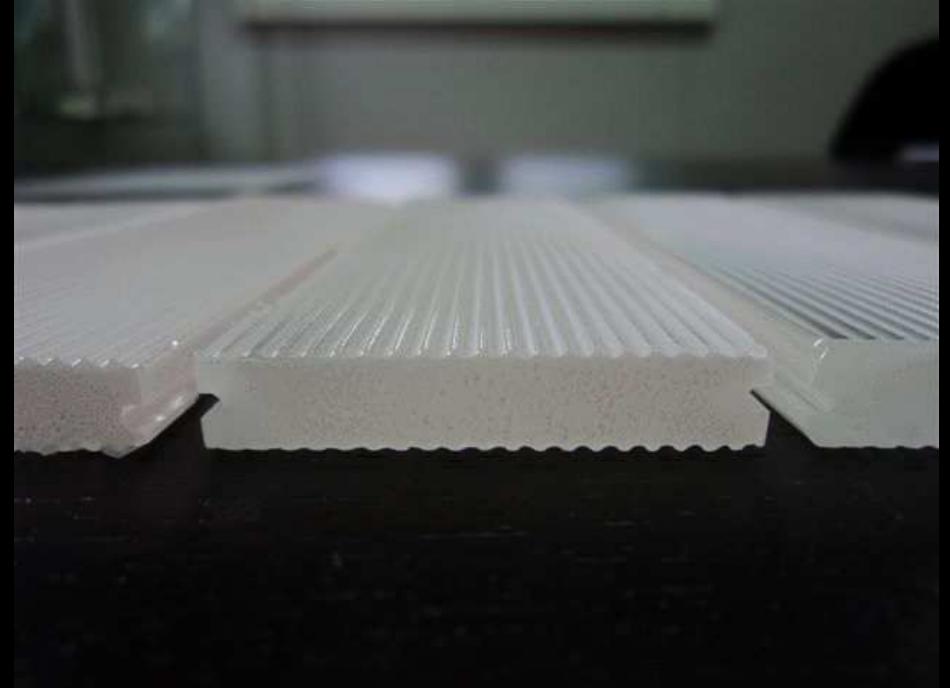

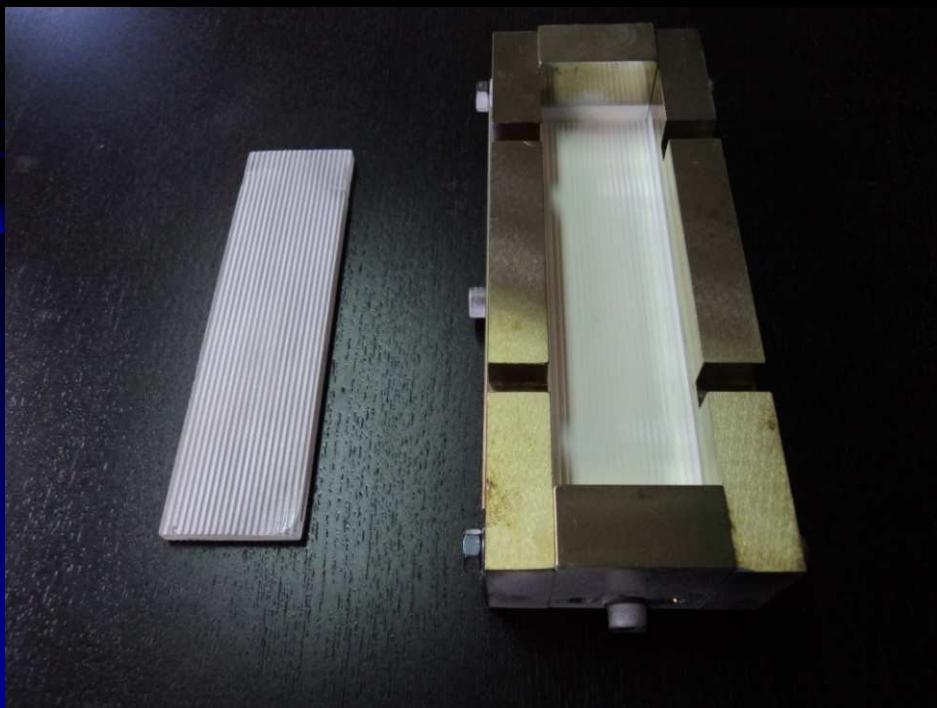

- Longer fabrication process
- Large waste

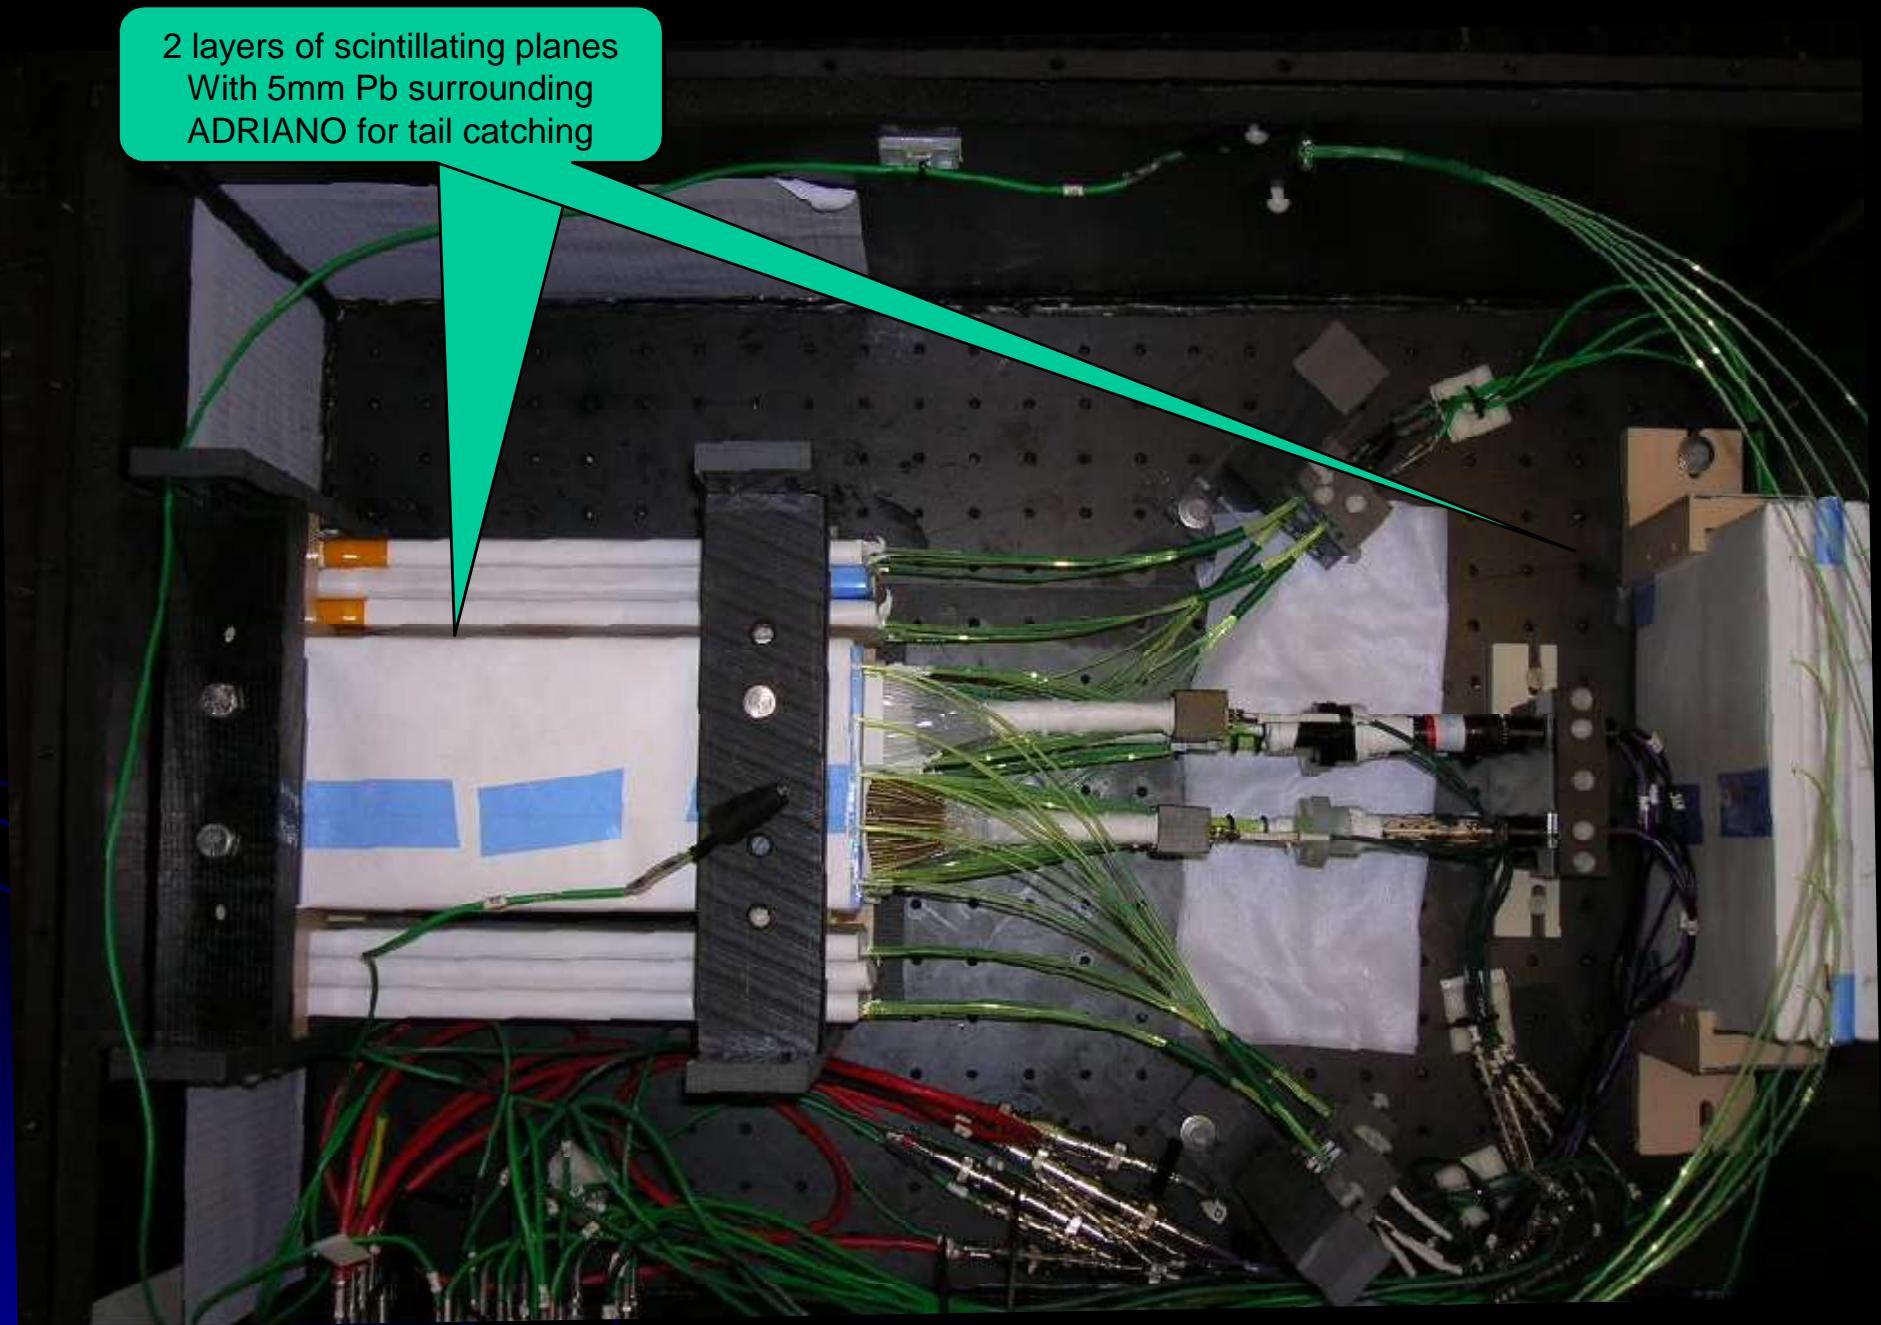

Fabrication Technology #2: Precision molding

- Pro
 - Cheapest and fastest (15 min)
 - Optical finishing with no extra steps
 - Low temp cycle (min effect on n_D)

- Cons
 - Molds are expensives
 - Lots of R&D

500 MeV e-

5 GeV e-/ π

500 MeV e-

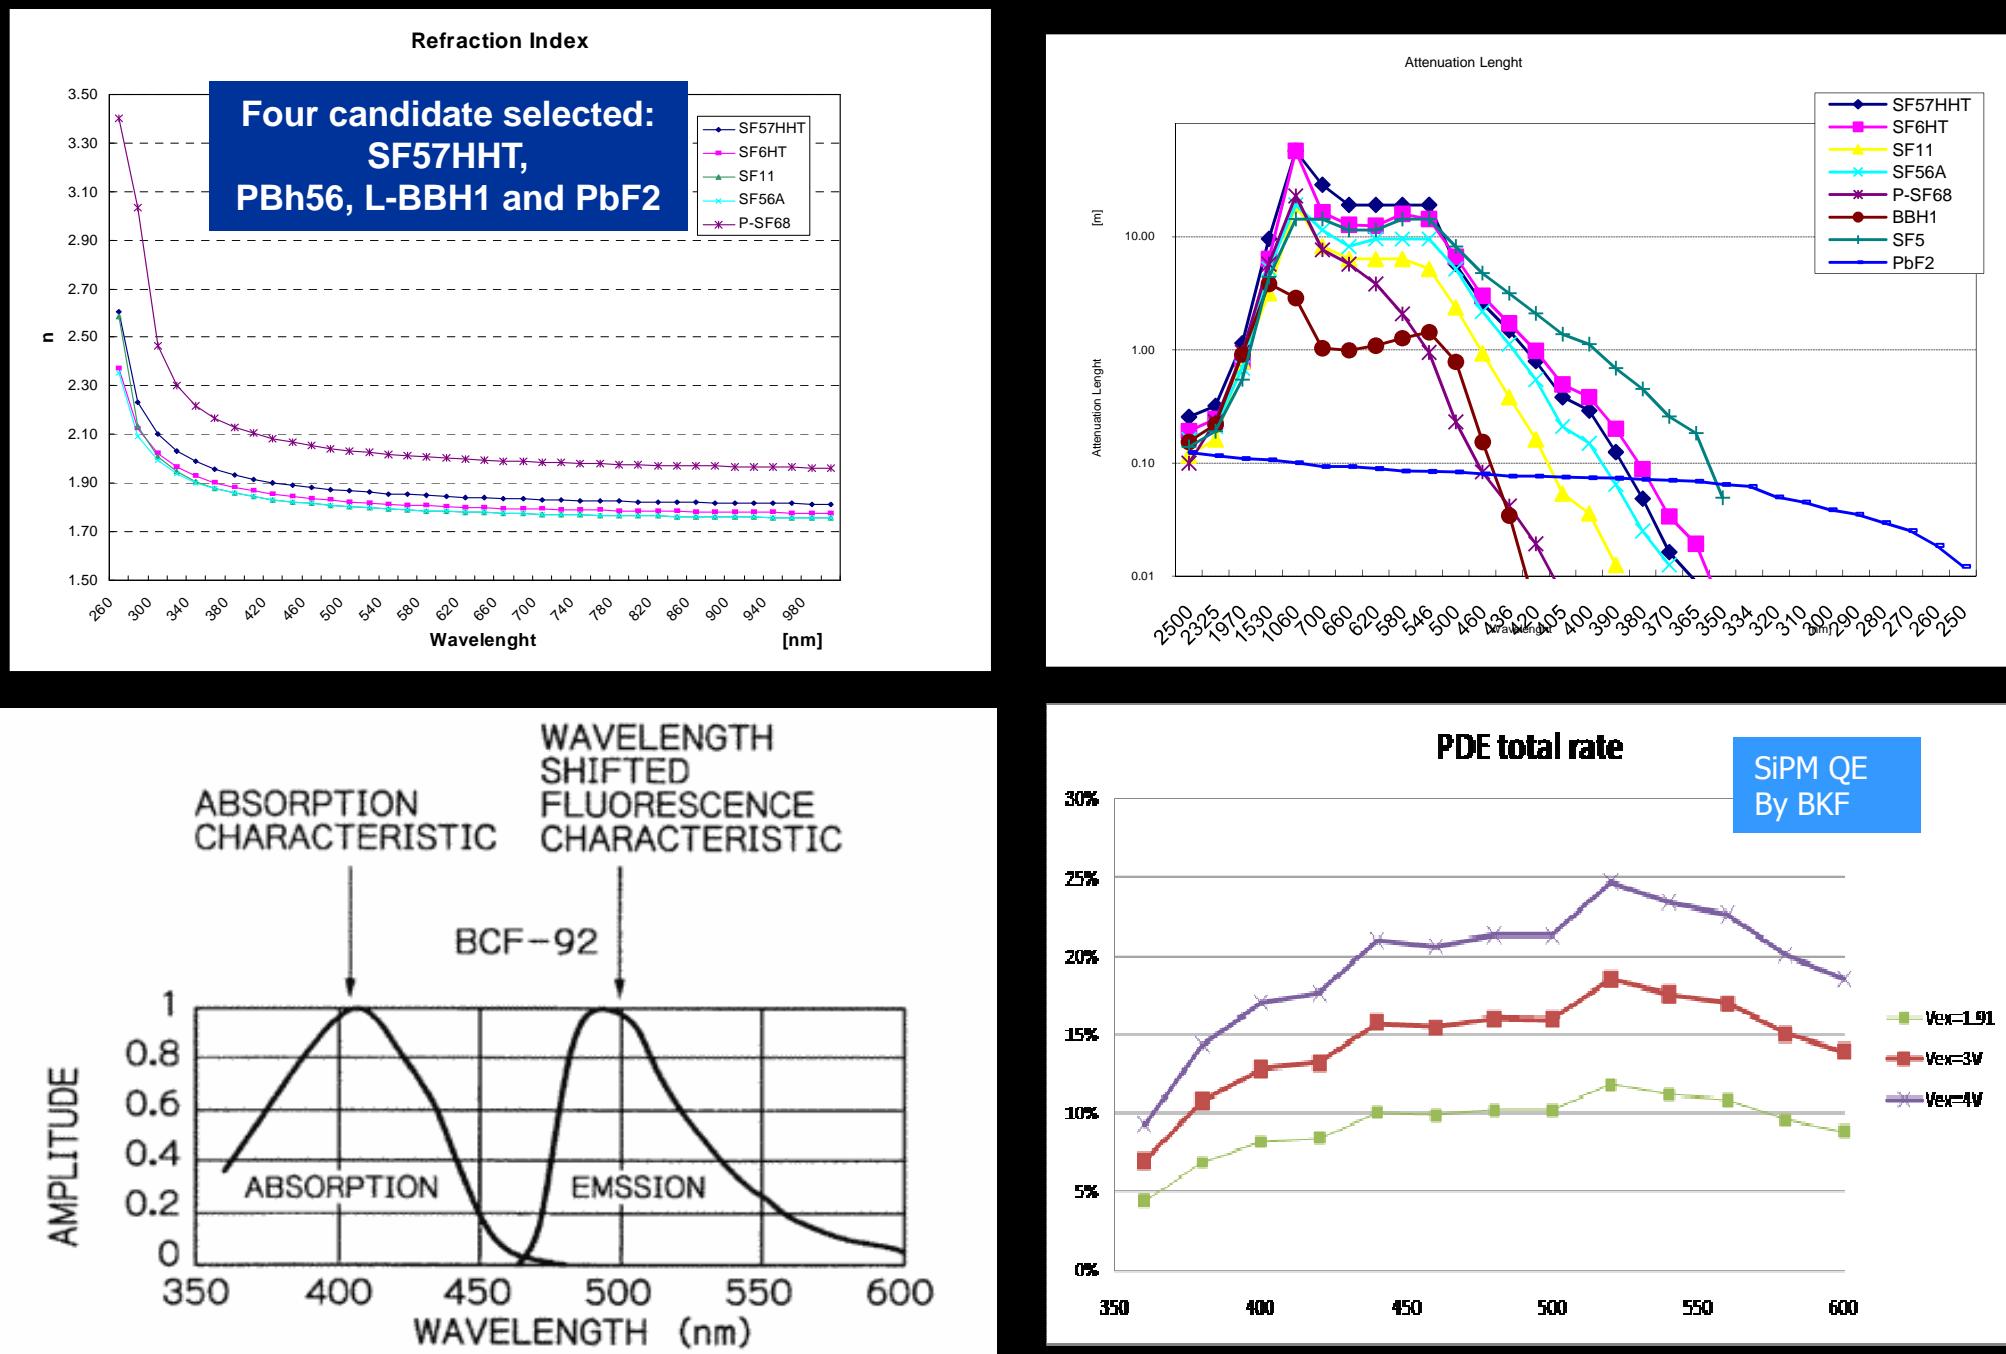

Conclusions

- *Three techniques are under consideration for a photon veto/calorimeter at ORKA: 1 sampling and two integrally active*
- *r-segmentation is preferred. Could switch to z-segmentation if light propagation time becomes an issue*
- **An integrally active calorimeter will easily provide at least 50% more light yield**
- Thin glass/crystals are employed as active absorber: require specific R&D
- R&D already under way under the auspices of T1015 collaboration (FNAL+INFN)
- ADRIANO technique already works for HEP: need dedicated optimization for lower energy experiment

Backup Slides

Optical Spectra in *ADRIANO*

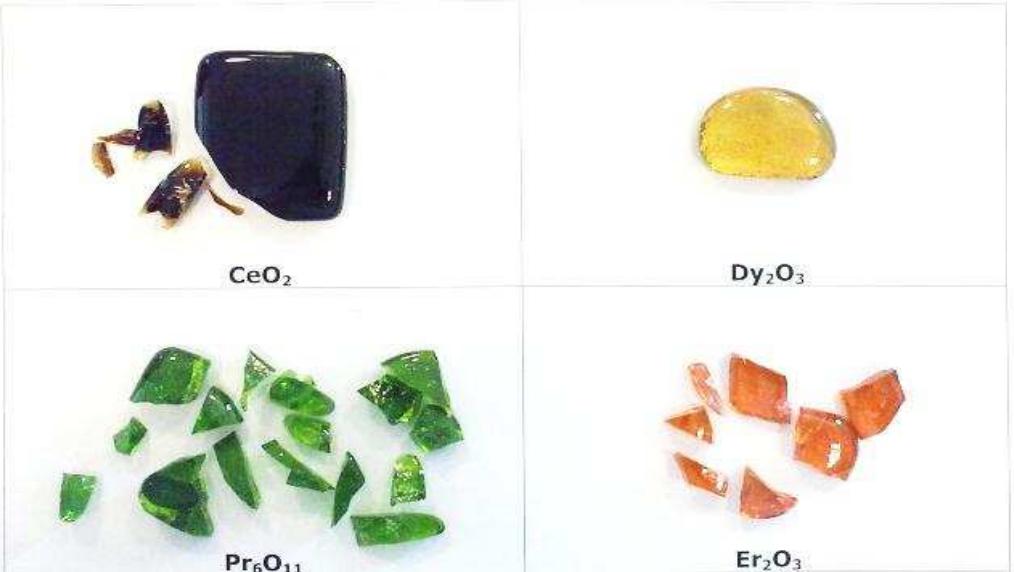

Scintillating Glass

- **Scintillation and Cerenkov at the same time in a totally homogeneous active absorber (not necessarily a good idea)**
- Major issues:
 - absorption lines in rare earths induce Č->S shift
 - Need high density glass
 - Slow scintillations (several tens ns)
- Separate the two problems:
 - Fix the optical problem by finding the correct ratio of oxides
 - Increase the density with proper vetrous matrix (BiO_2 and WO_2 under consideration)
- Current status:
 - Several rare earth oxides tested: Dy_2O_3 promising
 - BiO_2 glass OK (6.6 gr/cm^3), WO_2 unsuccesful (need high temp furnace)

Rare Earth Heavy Glasses

- Rare earths oxides + Ho_2O_3 + ZnO + P_2O_5 + B_2O_3 + SiO_2
- R.e. considered: CeO_2 , Dy_2O_3 , Nd_2O_3 , Pr_6O_{11} , Er_2O_3

Composition	Density (g/cm ³)
CeO_2	3,3776
Pr_6O_{11}	3,7445
Dy_2O_3	3,8851
Er_2O_3	4,0690
Nd_2O_3	4,2441

2011 Test Beam Setup at FTBF

From Dual to Triple Readout

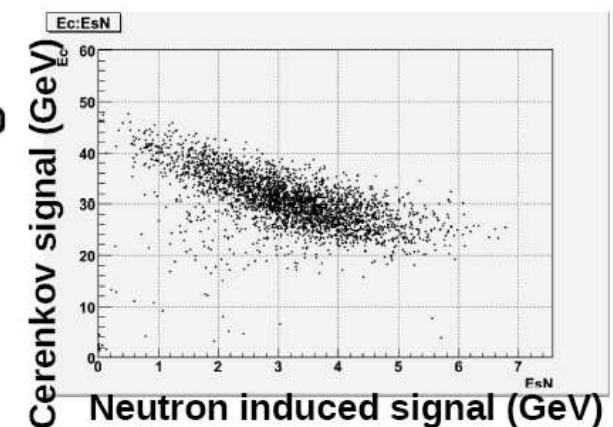

Disentangling neutron component from waveform

Time history of the scintillating signal

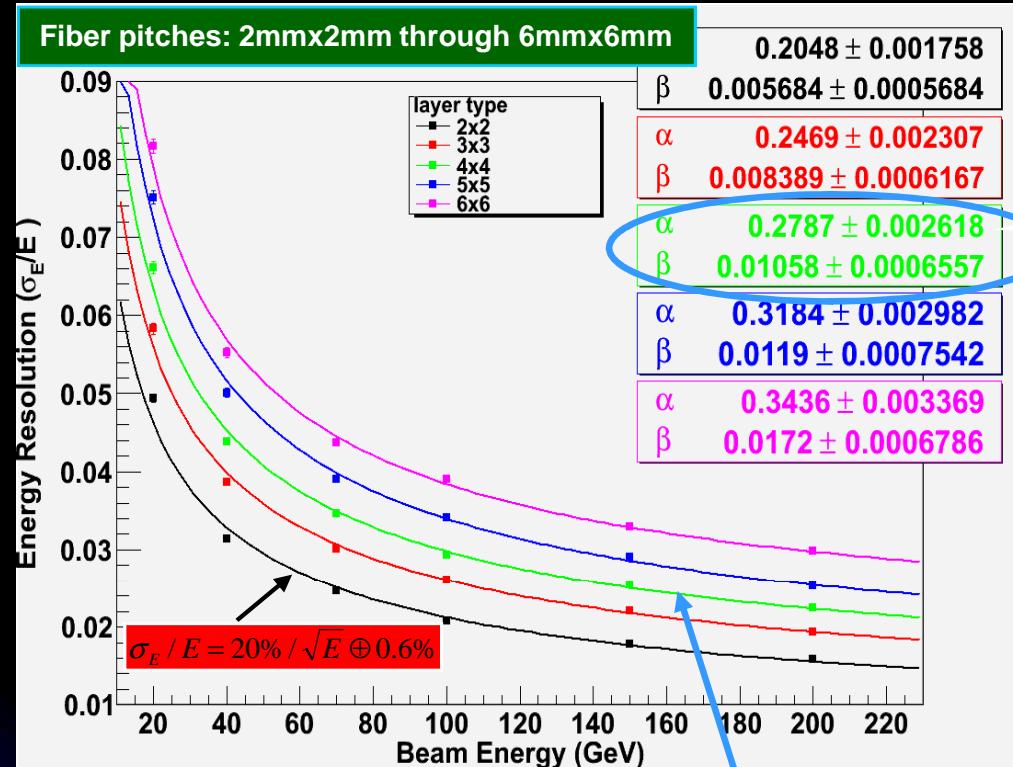

$$E_{\text{shower}} = \frac{S_{\text{fast}} - \chi C}{1 - \chi} + \sum S_{\text{slow}}$$

- The distribution has been fitted with a triple exponential function.
- After 50 ns only neutrons contribute to the signal.

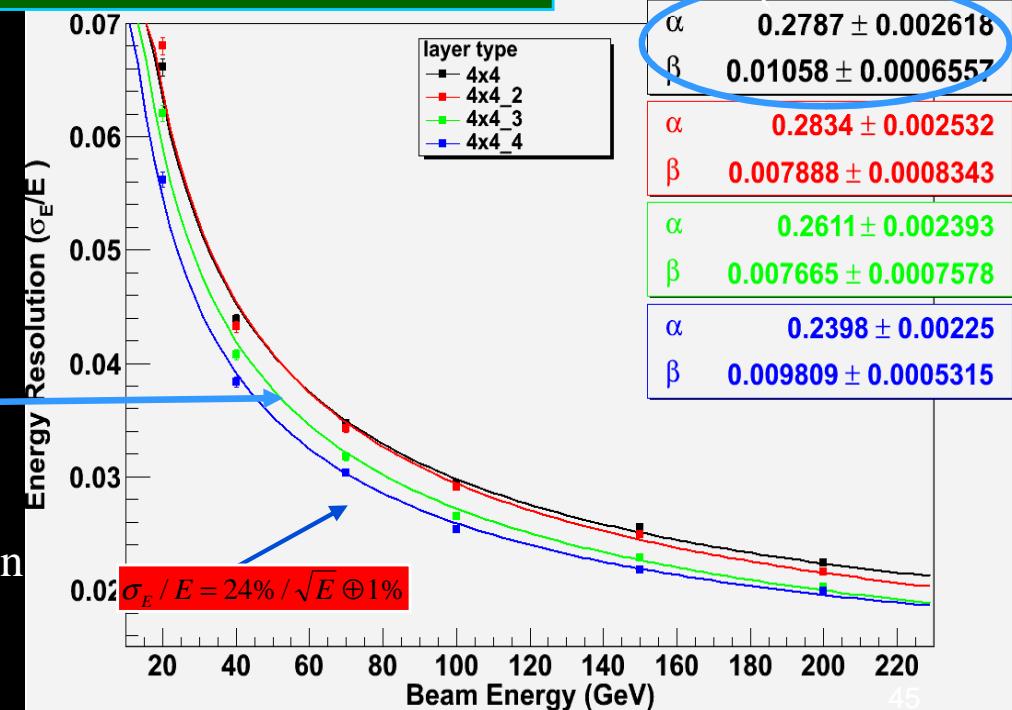

ADRIANO in Triple Readout configuration

Baseline
configuration

Pion beams

fiber diameter: 1mm – 1.4mm – 2 mm

Compare to ADRIANO in Double Readout configuration

Future Prospects

- First 2 year R&D on fabrication techniques already producing clear directions
- Precision molding technique is preferred (*ADRIANO*)
- Starting in year 2012 we will exploit
 - Laser-based technique coupled with diamond milling
 - Dedicated, high speed (< 30 min) molding machine with Pt-Ir coated ($R_a \sim 5-10 \text{ nm}$) molds
 - Photo-etching techniques
- Ohara sponsorship/partnership for bismuth optical glass (6.6 gr/cm^3 , $n_d = 2.0$) in progress: two strips (total 1.4 Kg) provided at no cost
- New Ohara heavy glass just tested at FNAL
 - 7.54 gr/cm^3 ; $n_d = 2.24$
- *ADRIANO2* (Cerenkov + scintillating glass)
R&D just starting. First results: $>600 \text{ pe/GeV}$
- Rare earth-doping tests under way at DIMA
- Heading toward a large prototype
 - 1,800 PMT appropriated from CDF
 - New experiments adopting *ADRIANO* (next slide)
